A good slate should be hard and tough, although liability to abrasion does not always indicate an inferior material. Some softness indicates good weathering qualities. If it is too soft it will absorb moisture, nail holes will become enlarged, and the slate becomes loosened. A good slate should give a sharp, metallic ring when struck. It should not splinter under the slater's axe, nor should it be tender or friable at the edges. It should not absorb water to any appreciable extent. An excellent test is to place a slate on edge half its depth in water, and if after 12 hours the line of absorbed water has reached the top of the slate, it should be rejected. If it does not rise more than $\frac{1}{8}$ inch, it may be considered as practically nonabsorbent. Good slate should not absorb more than one-half of 1 per cent. of its weight of water.

Slates are made of a wide variety of sizes, the larger sizes being used upon large areas of roof, such as factory buildings. The small sizes are more commonly used on residences and roofs of lesser area. A common size for house roof is from 6 x 12 inches to 10 x 14 inches.

Bands, ribbons or veins of a darker color running entirely through a slate are always dangerous, especially when they run along the length of the slate, as the slate will nearly always break or split along such a line. Even if this does not occur, these bands will generally decompose on exposure to the weather, causing a failure in the slate and a leak in the roof.

Slates are generally laid on wooden sheathing, preferably of fair thickness, matched and dressed, covered with tarred paper or felt. Sometimes the slates are laid on roofing laths nailed to the rafters at such intervals as to permit of nailing the slates to them. This, however, does not make as good a roof. On iron roofs slates are frequently laid directly on small purlins spaced like the roofing laths, and in this case the slate is fastened with wire passed through the holes in the slate and twisted around the purlins. Special forms of metal fasteners are also on the market for this purpose.

In laying slate on wooden sheathing copper composition or galvanized iron nails are ordinarily used, about $1\frac{1}{4}$ inches long, with ragged shank, driven through holes punched for the purpose in the slates, one near each corner. Some skill is necessary in properly nailing slates to a roof, as if the nails are not driven snug enough the slates will have some play upon the nails, while if they are the least bit too tight there is danger of the slate cracking, either when the nails are placed, or afterward, due to some movement in the roof surface.

The top courses of slate along all ridges and hips upon roofs, and also from 2 to 4 feet from gutters, should

be bedded in some proper cement that will make these parts entirely water proof, throughout all joints and miters. Care should be taken that the lower edge of every slate fit as closely as possible to the exposed surface of those below it, and that the vertical joints between slates be as close as possible, and occur only on the center line in the next course below.

Increased Use of Terne Plate Roofing.

A careful inquiry into the state of the roofing plate trade, says *Tin and Terne*, develops the interesting fact that the production has increased to a very marked degree of late. As a result of careful investigation it may be stated that the production of all grades of terne plate in the first six months of this year exceeded the production in the same period last year by fully 96 per cent., so that in the space of one year the production has very nearly doubled.

The indiscriminate use of any kind of terne plate for roofing a few years ago gave this form of roofing a rather bad reputation in some quarters. A good many of the producers were possibly not very well informed as to the proper processes to make a roofing plate which would stand the weather, and those makers who have steadily produced a good article had to suffer along with the whole trade. Added to this was the general lack of information as to how a roof should be taken care of in order to get the best results. There has of late been more thought given to the subject of paint, and there is no question that makers of terne plates are putting up a better article than formerly. The public also is learning to discriminate, and not use the cheapest grade obtainable, but is rather buying a better grade, which naturally gives better results and leads to increased consumption.

The evidence that the tendency is toward the better grade of roofing, as against lightly coated plates which should be used for temporary structures only, lies in the fact that while last year the quantity of terne plate produced which carried a coating heavier than, say, 18 pounds per double box was about one-fourth the total terne plate production, the proportion in the first half of this year is found to be close to one-third, the increase in the production of common ternes being probably a little under 85 per cent., while the increase in the production of the heavily coated plates was close to 130 per cent.

There is no question in the minds of those who have made a careful study of the subject that terne plate is the best form of roofing, all things considered, provided the plate is of good quality and the roof is properly taken care of. The trouble has been to make sure that good plates were being used on the building, and that the roof was properly taken care of afterward. It is not an easy matter for an architect to persuade a builder to employ the best material and architects have frequently refrained from specifying a particular brand, which they had reason to believe would be satisfactory, for fear of their motives being questioned. It is very gratifying to note that all signs point to a continued increase in the consumption of terne plate. While the production now does not constitute more than about one-eighth of the total production of tin and terne plate in the United States, a continuance of the increase noted in the past year will soon put this branch of tin plate industry in a more important place than it formerly held.

THE WAIS & ROOS PUNCH & SHEAR COMPANY advise us that they have changed their title and hereafter will do business under the name of the Cincinnati Punch & Shear Company. This change of title does not involve any alteration in the organization of the concern except that Christ. Wais is no longer connected therewith. The officers of the Cincinnati Punch & Shear Company are Henry Roos, president; Christ. Roos, vice-president, and H. M. Moore, secretary and treasurer. The above officers, with F. G. Cross, Julius Pfleger and C. B. Matthews, form the Board of Directors.

C. H. WILLISTON, Fall River, Mass., has the contract for laying the Gravel Roofing of the new mills of Cheney Brothers, at South Manchester.

Covering a Conical Tower with Sheet Metal.

BY WILLIAM NEUBECKER.

One of the most difficult jobs in flat or standing seam roofing is that of covering a conical tower. As the roof in question is round in plan and tapering in elevation, it is necessary to know the method for cutting the various patterns. In Fig. 1, let A B C be the elevation of a tower to be covered with flat seam roofing, using 10 x 14 inch tin at the base; the tinning to be laid on two-ply felting, and each sheet nailed with four $\frac{7}{8}$ -inch wire nails, the sheets being edged not less than $\frac{3}{8}$ inch to insure a good lock. Assuming that the tower at B C is 10 feet 6 inches in diameter, we will, at any convenient place at the building, strike a quarter plan, as for example that indicated by J E F, which will be used when getting out the pattern for the bottom of the gutter shown by dotted lines at B and C. The straight part of the gutter requires no pattern, and the slant part is obtained the same as for flaring work. As the diameter of the tower is 10 feet 6 inches and equals 126 inches, the circumference is obtained by multiplying this amount by 3.14, which equals 396 inches. As 10 x 14 inch tin plate is to be used at the base of the tower, the nearest width which can be employed and which will divide the base in equal spaces is 13.15 inches without laps, thus dividing the circumference into 30 equal spaces. This width of 13.15 inches and the length of the rafter A B or A C in elevation will be the basis from which to construct a triangle, in which all the patterns for the various courses will be laid off.

To obtain the patterns for the various courses proceed as follows: It should be understood that the diagram which will now be constructed will be enlarged so as to better show the methods involved. At any convenient place at the building stretch a piece of tar felting of the required length, tacking it at the four corners with nails to keep it from slipping. Upon the center of the felting strike a chalk line, as A B of Fig. 2, making it equal to the length of the rafter A B or A C of Fig. 1. At right angles to A B, Fig. 2, at either side, draw the lines B D and B C, each equal to 63.5 inches, being one-half 131.5 above referred to. From the points C and D draw lines to the apex A. As the width of the sheet used is 10 inches, and as $\frac{3}{8}$ -inch edges are put on each side, thus leaving $9\frac{1}{4}$ inches, measure on the vertical line A B $9\frac{1}{4}$ inches in succession, until the apex A is reached. Through the points thus obtained on A B draw lines parallel to C D intersecting the lines A C and A D, as shown. Then will the various patterns 1, 2, 3 and 4 be the net patterns for courses having similar numbers.

Take the shears and cut out the patterns on the felting and number them as required. For example, take the paper pattern number 1, place it on a sheet of tin, as shown in Fig. 3, and allow $\frac{3}{8}$ inch edges all around, and notch the corners, as shown by A, B, C and D. Mark on the tin pattern No. 1 29 more, as 30 are required to go around the tower. Treat all of the paper patterns from 1 to the apex in similar manner.

Of course where the patterns become smaller in size, as at the top, the waste from other patterns can be used.

In Fig. 4 is shown how the sheet should be edged, always being careful to have the narrow side toward the top, with the edges at the narrow and right hand side toward the outside, while the lower and left hand edges are edged toward the inside, all as shown in the diagram. Lay the sheets in the usual manner, breaking joints as in ordinary practice. As the seams are not soldered, be careful to avoid making "busters"—in other words, failing to interlock the joints.

After the entire roof is laid, and before "pounding down," or closing the seams with a mallet, take a tool brush and paint the locks with thick white lead, then close with the mallet. This will make a tight job.

The roof being covered, put the finial, D of Fig. 1, in position, when the job is ready for the painter. As the method used for obtaining the patterns for the various sheets in Fig. 2 is based upon the principle used in ob-

taining the envelope of a right cone, some readers may say that in accurate patterns the line from C to D should be curved and not straight, as shown. To those I would say that the curve would be so little on a small pattern where the radius is long that a straight line answers the purpose just as well in all practical work, for it would amount to considerable labor to turn edges on the curved cut of the sheet, and there is certainly no necessity for it. Supposing now that the tower shown in Fig. 1 were to be covered with standing seam roofing, the method of obtaining the pattern would be a little different. As the reader knows, standing seam roofing, when required in single sheets, is prepared by locking together sheets of the required number, the cross seams being soldered, the side edges then being bent up on each

Fig. 1.—Plan and Elevation.

Fig. 2.—Obtaining Patterns for the Various Courses.

COVERING A CONICAL TOWER WITH SHEET METAL.

side $1\frac{1}{4}$ and $1\frac{1}{2}$ inches respectively by means of the roofing tongs. Care should be taken when bending the standing seams that the cross seams do not crack, and to examine same before laying on the roof, as this is very often the cause of leaks which are very hard to find afterward. As the circumference of the tower at its base is 396 inches, and assuming that 14 x 20 inch tin plate is to be used at the base of the tower, the nearest width which can be employed and which will divide the base into equal spaces is 17.523 inches, without edges, thus dividing the circumference into 23 equal parts. Then will this width of 17.523 inches and the length of the rafter A B or A C in elevation be the basis from which to construct the pattern for the standing seam strip, for which proceed as follows: Let A B C D in Fig. 5 represent a 20-inch strip "knocked out," or locked together and soldered, using $\frac{3}{8}$ -inch edges; through the center of this strip draw the line E F. Now measure the length of the rafter A B or A C in Fig. 1, and place it on the line E F in Fig. 5, as shown, from

H to F. At right angles to H F on either side draw the lines F O and F L, making each side equal to 8 14-23 inch, being one-half of the 17 5-23 above referred to. From points L and O draw lines to the apex H. At right angles to H L and H O draw the lines H P, equal to 1 1/4 inches, and H S, equal to 1 1/2 inches, respectively. From points P and S and parallel to H L and H O draw the lines P D and S C respectively. Then will P S C D be the pattern for the standing seam strip, of which 22 more will be required. When getting out the balance of the 22 strips it can be accomplished in the quickest way as follows. Take the pattern just cut, lay it upon the roof or bench, and scribe a chalk line around the entire pattern; remove the pattern. Now start with a 14 x 20 inch sheet and tack it with nails at its lower end to keep it from slipping, as at L and O; then, having the chalk

Fig. 6.—Showing How to Cut the Metal.

Fig. 5.—Obtaining Patterns for Standing Seam Strip

COVERING A CONICAL TOWER WITH SHEET METAL.

line just scribed as a guide, lay the following sheets, being careful to use the waste as the apex is reached. After having "knocked out" 22 of these strips and soldered same, the pattern is laid over each one and accurately marked, cut and bent up. It is then laid on the tower, fastened with cleats and double seamed with the hand seamer and mallet in the usual manner. If the tower was done in copper or galvanized sheet iron, where 8-foot material could be used, as many sheets would be locked together as required; then metal could be saved and waste avoided by cutting the sheets as shown in Fig. 6, in which A B C D shows the sheet of metal and E and F the pattern sheets, the only waste being shown by the shaded portion.

Where the finial sets over the tower, as at D in Fig. 1, the standing seams are turned over flat as much as is required to receive the finial, or small notches would be cut into the base of the finial as to allow it to slip over the standing seams. Before closing the standing seams take a brush and fill seams with white lead, then close up tight, which will make a good joint.

Tin Plate Imports.

The official returns of the British Board of Trade for September, 1901, show that 9455 tons of Welsh tin plates were shipped from British ports to the United States during the month, as compared with 8508 tons in the preceding month and 6925 tons in September, 1900. The total shipments of tin plates from Great Britain to this country in the nine months ending September, 1901, amounted to 50,824 tons, as against 46,176 tons for the corresponding period of last year. The increase in imports of tin plates into the United States this year is attributable to the strike in the domestic tin plate mills, which caused a temporary scarcity of American plates and forced some consumers to use the foreign product. It is not likely that this rate of increase will be maintained during the closing months of the year, as the American mills are again in operation and are making deliveries to their customers.

The official figures of the Bureau of Statistics of the Treasury Department, just issued, show that the imports of foreign tin plates into the United States for the first nine months of 1901 amounted to 113,441,883 pounds, valued at \$3,404,286, as compared with 113,571,584 pounds, valued at \$3,895,584, in the corresponding period of last year. Thus it will be seen that the imports for the two periods were almost exactly of similar amount. The imports of foreign tin plates into the United States in the first nine months of 1899 amounted to 96,279,433 pounds, showing a material growth in the last two years, due to the shutting down of the American mills on account of strikes.

A New Tin Plate Enterprise.

On October 31 there were incorporated under the laws of the State of New Jersey the International Tin Plate Corporation, with a nominal capital of \$100,000. The title of the corporation indicates their purpose to manufacture in Europe, the United States and Canada. H. Herbert Andrew, J.P., managing director of J. H. Andrew & Co., Limited (Toledo Steel Works), Sheffield, England, one of the largest makers of fine steels in Europe, represents the foreign interests of the corporation, which is indorsed by Lord Charles Beresford, who has inspected the system and is chairman of Mr. Andrew's English company. This corporation will operate under the inventions of Messrs. Andrew and Allis, known as the Allis-Andrew system, which is protected by numerous patents granted in the United States and abroad. The domestic affairs are looked after by their president, Thomas V. Allis of Bridgeport, Conn., where the system was developed.

Alan Wood Company Improvements.

A short time ago it was announced that the Alan Wood Company, sheet manufacturers, of Conshohocken, Pa., had purchased property adjoining their plant and would immediately erect a \$1,000,000 steel plant. We are informed by President Howard Wood of the company that this plan has been abandoned, but that the new works would be erected in Plymouth township, which is just outside of Conshohocken. Work will be commenced immediately on this site for the erection of a 400-ton open hearth steel plant, consisting of five 50-ton furnaces. Four of these furnaces will be used continuously, producing two heats a day, and one will be a "spare" furnace. Plans are now being prepared and the works will be erected as soon as the material can be delivered on the ground. It is expected that they will be in operation in the fall or winter of next year. The location is such that material can be received and the finished product shipped over either the Pennsylvania or the Reading railroad. The company have purchased property adjoining their present plant and it is expected that the iron mills there will be enlarged next year.

THE G. B. WEST COMPANY, Harrisburg, Pa., manufacturers of Corrugated Sheet Iron Ornaments, lost heavily by a fire last week. Their entire plant was destroyed, along with valuable machinery.

Death of William J. Gordon.

William J. Gordon, a well-known inventor and manufacturer of tin and sheet metal workers' tools and machinery, died suddenly on November 4 at his home, 2450 North Broad street, Philadelphia. He was born in Philadelphia on November 4, 1835, and learned the trade of a machinist in Norris' Locomotive Works. In 1864 he established himself in business at Front and New streets as a manufacturer of tin workers' tools, dies and presses. Subsequently he formed a partnership with H. B. Gilbert, under the firm name of Gordon & Gilbert. The firm dissolved eight years ago, since which time Mr. Gordon had carried on the business alone. He is said to have invented the first machine known for riveting buttons on clothing, and many of his devices for the manufacture of cans and other tinware, and corrugated rain pipes are used in all parts of the country. In all he is said to have patented 65 different mechanical contrivances. Mr. Gordon was well known in Masonic circles, having been a member of Perkins Lodge, No. 402, F. and A. M.; Philadelphia Chapter, No. 169, R. A. M.; and Philadelphia Commandery, No. 2, K. T. In his early manhood Mr. Gordon was married to Hannah M. Vasey, who, with a daughter, survives him.

FLASHINGS.

It is reported that an independent Tin Plate mill will shortly be erected at Lisbon, Ohio. Negotiations looking to the establishment of such an enterprise are going on, and it is said that the necessary capital has already been secured.

THE Pittsburgh papers say that the labor leaders of that city regret very much the resignation of President D. G. Reid and Vice-President Warner Arms of the American Tin Plate Company. These officials were both regarded as friendly to organized labor, especially Mr. Arms, who bears a reputation for open dealing with the men. He was always regarded as considerate of their welfare and conservative in his dealings with them in times of strikes. It is said that during all the time he was interested in independent plants, before entering the combine, he never had a strike and always showed himself to be in sympathy with the men employed in his mills.

CAPITALISTS of Cleveland, Ohio, are in correspondence with the Board of Trade at Ashland, Ky., relative to the proposed establishment of a Corrugated Metal Roofing plant in connection with the new Sheet mill that is being erected in that city.

THE BARTLETT STEEL COMPANY of Joplin, Mo., have been organized to take over the business of John L. Bartlett. The business of the company is that of jobbers in Structural Steel, Bar and Sheet Iron, Castings, &c., and their salesmen will cover the territory in South-western Missouri, Kansas, Arkansas, Indian Territory, Oklahoma and Texas. The officers of the company are: E. O. Bartlett, president; John W. Harris, vice-president; Jerome B. Grigg, treasurer, and John L. Bartlett, secretary.

S. L. HINCHCLIFFE, New Britain, Conn., has a contract for tinsmithing on the new East Main Street School Building, and on a block of buildings for W. S. Bradley in that city.

JOHN THOMAS, formerly a roller at the mill of the Republic Iron Company on the South Side, Pittsburgh, has gone to Waukesha, Wis., with a force of 40 men to start the new independent Sheet mill at that place. Nearly all the men came from Chartiers, Pa., and were formerly employed at the Sheet mill in that town, which has been moved to Leechburg.

H. WEISS & Co., 20 Cliff street, New York, are sending to the trade a 32-page catalogue devoted to the Niagara Tinsmiths' Tools and Machines. The firm carry in stock, ready for prompt shipment, all the machinery necessary for equipping a tin shop or cornice maker's shop. The catalogue shows Tin Folders of various designs; Burring and Turning Machines, Beaders, Setting Down Machines and Crimpers, all adapted for use in an

adjustable bench standard that can be attached to any work bench. Forming Rolls and Stove Pipe Formers are also shown. One page is devoted to a variety of Tinners' Stakes, made of wrought iron with steel faces. Bench Plates, Bench Shears, Hand Snips, Slitting Shears and Pipe Cutting Shears are followed by Raising Hammers, Scratch Awls, Rivet Sets and Headers, Groovers, Chisels and Hollow Punches. Roofing Tools and Fire Pots are also shown, as well as Gutter Beaders, Circular Shears and different styles of Squaring Shears, Lever Shears and Punches. The catalogue also shows Power Presses and Cornice Brakes.

THE AMERICAN CAN COMPANY have purchased the Loyhed Tinware Company of Seattle, Wash. The Can company now own factories on the Pacific Coast at San Francisco, Los Angeles, Astoria, Fairhaven and Seattle.

SEVERAL important changes have recently been made in the management of the Mossberg & Granville Mfg. Company, Providence, R. I. At the recent election the following, who have not heretofore been associated in the management, were made directors: W. W. Orr, V. I. Cunnock, E. C. Moen, A. R. Whitney, Jr., and Joseph W. Harriman, all of New York, and Elisha H. Howard of Providence. The Board of Directors organized by electing Howard C. Smith of New York, president; Elisha H. Howard, vice-president, and E. C. Moen, secretary and treasurer. V. I. Cunnock was made chairman of the Executive Committee. The resignation of W. W. Gibbs, for some time past general manager, was accepted and in his place George A. Clark, formerly of Lowell, Mass., has been appointed. The business of the company at the present time is in a flourishing condition, and various new patterns of Tools and Machines have been added to their already very extensive catalogue. The New York office of the company is at 100 William street.

THE AMERICAN CAN COMPANY, 21 State street, New York City, are about to make many improvements to their plants in Baltimore, Md. The factory of the R. Tynes Smith Company is to be made one story higher and modern machinery installed, and a large warehouse will be erected at the works of the Norton Tin Plate & Can Company.

E. VAN NOORDEN COMPANY, Boston, Mass., are building 500 Single Pitch Galvanized Iron Skylights, about 8 feet square, for the Atlas Tack Company, Fairhaven, Mass. They are also at work on an order for about half of that quantity for the Soule mill at New Bedford, Mass.

THE ALEXANDER MFG. COMPANY, Canonsburg, Pa., are erecting a plant for the manufacture of the Acme Stove Pipe Elbows and Drip Pans. The company have a capital stock of \$12,000.

ACCORDING to the *Iron and Coal Trades Review* of London, the Tin Plate industry was first introduced into Wales by Capel Hanbury, who in early life had traveled in Norway and Sweden, where it was then in a more advanced stage than in England. The method of rolling Iron into large Plates which were used for roofing houses had been in existence in those countries for some time. Rolling mills were then in existence in Wales, but they were not of the kind used in Norway. On the return of Mr. Hanbury to England he leased a large tract of land at Pontypool, in South Wales, for a term of 99 years, and set up rolling mills in connection with his furnaces. These mills were an improvement on those of Norway, rolling Plates much thinner than the Norwegian Plates. In time the Black Plates were introduced and then coated with tin, which marked the genesis of the Welsh Tin Plate trade. Mr. Hanbury is said to have been the first maker of Tin Plates in Wales.

United States Consul Hill of Amsterdam, Holland, reports that the project of draining the Zuider Zee has been withdrawn from the States-General by the new ministry, thus being disposed of probably for a long period. The state of the Dutch budget renders such an undertaking at this time unadvisable; besides, the fall in the price of land has diminished the demand for new agricultural holdings.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

CONSTRUCTING A CHURCH FURNACE.

From F. G., Detroit, Mich.—I have read the request for assistance made by "A. S." in *The Metal Worker* of November 2 and am of the opinion that he will save little money by endeavoring to utilize his box stove for the hot air furnace in the church. He would be better off if he purchased from some manufacturer a furnace having a capacity sufficient for the purpose. He does not give the points of the compass of his church, which are very important in locating a furnace for heating. If the pulpit is in the north or the west end the furnace may be located almost directly under it, and have a 24 x 36 register placed in the floor in front of the pulpit, connected with the furnace by means of a 24-inch pipe; or two 16 x 20 inch registers may be used, connected with the furnace by means of two 16-inch pipes. All of these pipes should have tight dampers in them if the furnace is to heat the basement. Tight dampers, however, if they do not receive the proper attention, may lead to burning out the furnace under some conditions.

For heating the basement an opening should be left in the hot air pipe of a size equal to its full capacity. This opening can be covered by means of a suitable door. The cold air supply for the furnace can be arranged so as to take it from out of doors, from the church floor and from the Sunday school room. In any case the cold air ducts should not be larger than 24 inches in diameter, or 20 x 22 inches square. The cold air register or registers may be placed in the church floor beside the hot air registers. This will exhaust the cold air from the floor of the church and take it down to the furnace to be heated and sent back, to facilitate the heating of the church before the congregation assembles. This exhaust pipe should have a tight damper in it, which should connect with the cold air pipe from out of doors. This also should have a tight damper in it, to close it when the air has been taken from the church. Just before these two cold air pipes connect with the furnace a door should be put in the side, having an area equal to that of the pipe. Then when the Sunday school is to be heated the cold air will be taken from the floor, passed through the furnace and discharged through the door opening into the hot air pipe.

Some difficulties are presented in the heating on account of the flues. If, however, they have a strong draft and the pipe connections are carefully made, so as to prevent the cold air from coming down one chimney and going through the furnace around and up the other, two chimneys may be used without disadvantage. If the draft is strong some additional heating surface can be put within the brick chamber by running an 8-inch elbow up from the top of the box stove and carrying a pipe 8 inches in size horizontally above the stove to the front of the brick chamber. Here a tee should be placed, tapering into two 6-inch outlets, and one of these 6-inch pipes should be run back on each side of the hot air chamber, carried through the wall of the furnace and attached to the smoke pipe connected with the flue. By this means either 6 or 8 inch pipes may be used and a considerable additional heat derived to aid the box stove in doing the heating. If the elbow which rises from the collar at the back of the stove connects with each of these side pipes in the chamber a more direct draft can be secured when the fire is started. But a tight damper should be placed in each of the connections, so as to force the indirect draft when desired.

From R. N., North Dakota.—In reply to the request of "A. S." in *The Metal Worker* of November 2 I offer a few suggestions on the construction of the furnace for heating his church or for the utilization of his box stove.

From descriptions of successful hot air furnace plants which have appeared in *The Metal Worker* it is very clear that the amount of surface which the furnace must expose to heat the air that is to maintain the church at a comfortable temperature depends almost entirely on the surface the church exposes. The dimensions of the building are given as 30 x 50 feet, with a 14-foot ceiling. It is a simple matter to find from these dimensions that the outer wall of the church would expose a surface of 2240 square feet and the building would contain 21,000 cubic feet of space. To heat this amount of air and to supply the heat that would be lost through the wall and glass surface a given amount of surface must be provided in the box stove. If the wall surface is reduced to a surface equivalent to glass in its heat losing power by dividing the amount by ten, it would give 224 square feet of equivalent glass surface.

As the box stove will use wood for fuel it can be safely relied upon to maintain its surface at as high a temperature as is desirable in a furnace for warming air. Under the circumstances I would calculate that 1 square foot of surface in such a furnace would take care of 4 square feet of equivalent glass surface. This would make it necessary to provide between 50 and 60 square feet of surface in the box stove and the pipe leading from it that might run around the brick chamber which incloses it. In house heating 1 square foot of heating surface will take care of about 250 cubic feet of space, but in a church it will take care of more space. If it is estimated that 1 square foot of heating surface in the furnace will heat 400 cubic feet of air in such a building, it can be readily seen that the box stove used must have something over 50 square feet of surface. Virtually the sides and back of the stove will be all that there is available as heating surface, and as the box stove is 5 feet long, it is probably 3 feet high, which would give 15 square feet of surface for each side and 6 feet of surface in the back, or 36 square feet of surface in the stove proper, as the top is of little use for heating air. If an 8-inch pipe is run up from the stove and around the chamber at least 10 lineal feet of smoke pipe would be used, exposing a surface of 20 square feet. This, in addition to the surface exposed in the stove, will probably bring the surface up to the amount necessary according to my figures.

I have calculated some of my heating work along similar lines to that presented, but if my figuring is not borne out by the experience of others I should be glad to have them point out its defects and suggest the changes that I should make. This will, I am satisfied, be of interest to "F. G.," as well as an advantage to me, and possibly to many other furnacemen.

The brick chamber used in inclosing the stove should have its walls not over 4 inches away from the stove at the projecting parts of the stove. This will give an air space at the most restricted point having an area of over 600 square inches through which the air may rise to the hot air pipes and enough to fill four 14-inch pipes or a less number of larger pipes.

SIZE OF RADIATORS AND VENTILATORS.

From Y. I., Carbondale, Pa.—I have a room to heat and ventilate in a private hospital which contains 8400 cubic feet of space. It is located on the second floor and is to be heated by low pressure steam by means of direct-indirect radiators. I want to know how many square feet of radiating surface should be supplied to do the work, and also what should be the size of the openings under the windows to supply the fresh air to the four radiators to be placed in the room? What sized outlet should the room have to ventilate it? Should the ventilating flue run to the ventilator in the attic be heated by a steam coil to draw off the foul air? In case the ventilator is aided by the steam coil, is it necessary to reduce the size of the ventilator in the roof and make the smaller ventilating pipe or pipes connect with it?

Note.—We shall be glad if any of our readers who have had experience in similar work will give their views

as to the number and size of radiators that should be used for this work. It is probable that more information would be desirable in order to treat this problem satisfactorily. If the room is just under the roof and exposed on three sides more radiation would be required than if it were only exposed on one side and had another story above it. For a room of this character, if 1 square foot of radiation is provided for every 50 cubic feet of space, 170 square feet of direct radiation would be required. Indirect radiation, however, owing to the fact that it has to warm fresh air from out of doors, is apportioned on a basis 25 per cent. greater than for direct radiation; therefore, if indirect radiators were used, the surface should be not less than 215 square feet. Owing to the fact that a ventilating flue is to be provided, and in a hospital building, it is well to provide for a frequent change of air. It would be desirable to provide 250 square feet of surface in the radiators, and if four radiators were used, each radiator should present a surface of not less than 60 square feet. The size of the air inlets to the radiators would be governed somewhat by the number of times per hour the air has to be changed. Under ordinary circumstances, if each of the 60-foot radiators were supplied with air to fill an opening $2\frac{1}{2} \times 12$ inches or 3×12 inches, a sufficient volume of fresh air would be supplied. If more ventilation is desired, the supply would be based on $\frac{3}{4}$ square inch area in the air inlet duct for each square foot of surface in the radiator. The openings to the ventilating flues should have an area equal to the combined area of the cold air inlets. The registers should be placed near the floor and a steam coil in the ventilator. If a steam coil is placed in the ventilator, neither the main ventilator nor the branches into it should be reduced in size. The steam coil should be used if possible, as it will create a positive exhaust current.

TROUBLE WITH A CHIMNEY.

From W. M. B., York, Pa.—Will *The Metal Worker* or some of its readers give me some information that will aid me in overcoming the trouble with the chimney

Trouble with a Chimney.

shown in the accompanying sketch? This chimney will not draw as it should. It has now been raised twice, so that it is 18 inches higher than the front mansard roof, yet there is still trouble with the range which is connected with it. The chimney is on the outside wall on the west side of the house and is 9×9 inches in size. Thinking that perhaps the trouble might have been in the range that was used, another range was connected with it, but with no better results. I should be glad to know what is the probable cause of the trouble and what I may do to overcome it.

Note.—Many of *The Metal Worker's* readers have had experience with similar troubles and can doubtless suggest something that will be of benefit. In the meantime we would suggest that the range be connected with the chimney by a pipe the full size of the collar and not less than 6 inches in diameter. At the point where the stove pipe connects with the chimney care should be taken to see that it is as near air tight as possible all around and that the pipe does not extend so far into the chimney as to cut off the draft. The chimney should be examined to see if the mortar has fallen away from the

bricks so as to allow the air to enter it without passing through the fire. There is one important principle to be observed, and that is to see that no air goes out of the top of the chimney except that which goes in through the draft slide in the ash pit of the range.

If this chimney is more troublesome when the wind blows, it is probable that it is still not high enough to escape the influence of the air currents striking on the other parts of the building. Not infrequently, however, similar trouble may be caused by the wind currents blowing across the top of a higher story at a distance. When the air, after passing over the higher story, takes a downward turn on reaching the lower part of a building, it is liable to cause a downward air pressure on the top of a chimney some distance away. If the trouble comes when the wind is blowing hard a chimney cap may help to avoid it. If, however, the main trouble is experienced when there is but little wind, the provision of a larger smoke pipe with a perfectly tight chimney connection and the cementing of all of the joints between the bricks of the chimney will be necessary. If this does not accomplish the desired result it is probable that the chimney will have to be still further increased in height.

TRADE NOTES.

THE JOSEPH DIXON CRUCIBLE COMPANY, Jersey City, N. J., have just made a shipment to their San Francisco branch of 14 double truck loads of their Graphite productions, having a total weight of 85,000 pounds.

A FIRE occurred in the shop of the Garden City Nickel Plate Works, at 253 Canal street, Chicago, on October 27, which did damage to the extent of \$2000.

THE ASHLAND EMERY & CORUNDUM COMPANY, incorporated recently in New Jersey with a capital stock of \$3,000,000, represent a combination composed of the Ashland Mills Emery Company of Perth Amboy, N. J.; the Diamond Mills Emery Company of Philadelphia, the Jackson Mills Emery Company of Easton, Pa.; the Walpole Emery Mills of South Walpole, Mass.; the Hampden Emery Mills of Chester, Mass., and the Levant Emery Company. The combined corporation own Emery mines in Chester, Mass., and Peekskill, N. Y. It is said that the output of the concern will amount to about 12,000 tons of crushed imported Emery, 5000 tons of native Ore and 2000 tons of Corundum.

WE have received from the Pneumatic Tool Company, 632-640 Monadnock Block, Chicago, Ill., a copy of their catalogue No. 15, just issued, which is claimed to be the most complete catalogue of Pneumatic Appliances ever published. A feature of the catalogue is a number of excellent half-tone engravings showing the company's tools in operation. These cuts, they advise us, are made from photographs taken from important buildings and other structural work on which the company's tools have been used. They call attention to the fact that they were awarded the only gold medal for Pneumatic Tools, and also a silver medal for their exhibit at the Pan-American Exposition, at Buffalo. The tools shown include Riveting Hammers, Calking and Chipping Hammers, Riveters, Air Drills, Boring Machines, Painting Machines, Compressed Air Hoists, Pneumatic Cranes, Air Compressors, &c.

THE foundations for the two largest buildings for the new plant of the New Castle Stamping Works, New Castle, Pa., have been finished and the brick work has been started. The buildings will be large structures and work will be pushed as fast as possible.

THE Solder manufacturing plant of E. M. Lang & Co., at Eastport, Maine, was destroyed by fire on October 25, involving a loss of \$3500. We are advised by the company that they will rebuild the plant without delay.

For polishing aluminum an English contemporary recommends either rum and olive oil, a paste made of fine emery and tallow or an application of chalk and rouge.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin is dull and weak, but without change in price.
Copper prices are unchanged; demand is slow and spot Copper scarce.
Pig Lead is inactive, but firm.
Spelter is quiet and strong.
Antimony is unchanged.
Nickel continues firm.
Aluminum is active and unchanged.
Tin Plates are in good demand, with spot in scarce supply; jobbers' prices for Cokes are down 25c. a box.
Sheets are still in active demand and scarce, with prices strong.
Old Metals are rather more active, but prices are unchanged.
Sheet Copper is active and firm.
Foundry Iron is strong, with large demand and upward tendency.
Hardware continues in good demand, with prices well maintained.
Plumbers' Supplies are moving in good volume and prices are strong in all lines.
Wrought Iron Pipe prices are firm, and scarcity of heating sizes continues.
Malleable Iron Fittings, Class A, have been advanced 10c. per lb. on list.
Stove Pipe is very active and firm in price.
Wire Nails are in good demand, but prices are irregular and slightly lower.
Cut Nail manufacturers reaffirmed prices.
Wire is active and unchanged.
Window Glass in small sizes is lower in price.
White Lead prices are being cut to some extent.
Spirits Turpentine is ½c. a gallon lower.
Linseed Oil prices are irregular; demand active for small lots.
Manila Rope has advanced 1c. a lb.

METAL MARKET.

NEW YORK, November 8, 1901.

Pig Tin.—The market for Pig Tin has been dull and uneventful during the week under review. The amount of business transacted for consumptive account was very small, consumers limiting their purchases to what they need for immediate use. Speculative interest has also been dormant. Prices have sagged throughout the entire week and the market closed dull and weak. Straits Pig in small lots is quoted at 25½c. to 26c. per lb. According to the October statistics computed by the New York Metal Exchange, the total visible supply of Tin on October 31 was 194 tons above that of October 31 of last year.

Copper.—Owing to the fact that no actual developments have yet occurred, interest in the situation is acute. Consumers are more cautious than ever, with the result that very little metal is changing hands. The impression seems to be increasing in the trade that the present prices cannot be maintained very much longer, notwithstanding that leading interests in the Copper market assert that there will be no decline this side of January. Spot Copper is still scarce and prices so far have been strictly maintained. Lake Ingot in small lots is quoted at 17¼c. to 17½c. per lb., and Casting Copper at 16¾c. to 17c.

Sheet Copper.—The demand for Sheet Copper keeps up in good volume and the mills are turning out a considerable product, which is said to be going into consump-

tion nearly as fast as made. Prices are firm, Sheet Copper from store being quoted on the basis of 21c. per lb.

Pig Lead.—The market for Pig Lead continues quiet but steady. Consumers are buying little beyond the limits of their current needs. American Pig in small lots is quoted at 4.62½c. to 4¾c. per lb. It is reported that a meeting of producers of Lead has been called for November 25 in New York City, to discuss the question of prices and production. The matter of curtailing the output will, it is said, be brought up, as there is now a considerable surplus of Lead on hand. St. Louis advices report that the Pig Lead market continues on the same basis as reported last week, both as to demand and price.

Spelter.—The market remains quiet but firm, owing to a continued scarcity of spot stock. Prices are unchanged from those given in our last report, good Western brands in small lots being quoted at 4.55c. to 4.60c. per lb. St. Louis advices report a good demand and no change in prices during the week.

Sheet Zinc.—The demand for Sheet Zinc is of ordinary type, and prices are without change, jobbers quoting 600-lb. cask lots at 6¾c. per lb., and smaller quantities at 7c.

Antimony.—No change has taken place in this metal, for which the demand is of fair proportions. Cookson's in small parcels is quoted at 10½c. to 11c., and Hallett's 8¼c. to 9c. per lb.

Nickel—Is unchanged, prices continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—An active demand for Aluminum continues, and prices remain at 37c. per lb. for small lots of No. 1 Ingot, guaranteed 99 per cent. pure, and 35c. for 100-lb. lots.

Tin Plates.—The situation in Tin Plates is unchanged and the market shows no features of special interest. The demand is about of the average amount for the season of the year and includes all classes of Plates. Deliveries on back orders are coming in slowly and the stringency which prevailed for some time past is gradually disappearing. The demand in this market is confined mainly to small purchases for immediate use. The American Tin Plate Company are selling up to the end of the first quarter of next year at prices prevailing for some time past. Jobbers' prices for small lots of American Bessemer Coke Plates, IC, 14 x 20, in New York or corresponding points rule about 25c. per box lower, at \$6 to \$6.50 per box, IX being quoted at \$7 to \$7.50.

Sheets.—The demand for Sheets is still very active and deliveries are about as hard to get as at any time during the year. The mills are still from two to three months behind on orders. Prices continue quite firm, jobbers quoting No. 27 One Pass Cold Rolled Soft Steel Sheets at about 4.15c., and Galvanized at 65 to 67½ per cent. off the list.

Chicago advices are as follows: Steady progress is made toward a resumption of normal quotations on Sheets from store because of more generous receipts. The latter, however, do not include all sizes and for some sizes there is continued scarcity. No. 27 Common is now selling at 3.50c. to 3.75c. Galvanized also is slightly lower, quotations ranging from 65 and 10 to 70. Tin Plates are arriving somewhat more freely and famine prices are slowly receding.

Old Metals.—A rather more active demand for Old Metals is noted, particularly for Scrap Iron, but prices have not advanced. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb. 14¾c.
Light and Tinned Copper.....	per lb. 12¾c.
Heavy Brass.....	per lb. 9¾c.
Light Brass.....	per lb. 7¼c.

Lead	per lb.	4 c.
Tea Lead.....	per lb.	3 1/2 c.
Zinc	per lb.	2 3/4 c.
No. 1 Pewter.....	per lb.	17 1/2 c.
No. 2 Pewter.....	per lb.	8 1/2 c.
Tin Plate Scrap, per gross ton.....		\$6.50 to \$7.00
Wrought Iron Scrap, per gross ton.....		10.50 to 11.00
Heavy Cast Scrap, per gross ton.....		10.25 to 10.50
Stove Plate Scrap, per gross ton.....		7.25 to 7.50
Burnt Iron, per gross ton.....		5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—From present appearances the usual dullness during the closing months of the year will not be felt at this time. All sales agencies report the demand sufficient to keep furnace stocks very low. That consumers also have little stock on hand is shown by the constant pressure for prompt delivery. The nearby furnace companies, who usually carry considerable Iron on hand, are all reporting themselves practically bare of stocks. We quote: No. 1, \$16 to \$17.50; No. 2 X, \$15.15 to \$15.75; No. 2 Plain, \$14.65 to \$15; Tennessee and Alabama brands, No. 1 Foundry, \$15.50 to \$15.75; No. 2 Foundry, \$14.75 to \$15; No. 1 Soft, \$15.50 to \$15.75; No. 2 Soft, \$14.75 to \$15; No. 3 Foundry, \$13.75 to \$14; No. 4 Foundry, \$13.50 to \$13.75.

CHICAGO.—The number of inquiries for deliveries of Pig Iron up to next summer is large and many of them are being closed. The business is shared by the Northern and Southern furnacemen alike, the orders being for approximately 1000 tons each. The trade in small lots is equally satisfactory. There is an absence of large orders, all the heavy consumers apparently having bought for some time ahead. Makers are well stocked with orders and the temper of the market is strong. Prices are unchanged, as follows:

Lake Superior Charcoal.....	\$17.00 to \$18.00
Local Coke Foundry, No. 1.....	15.25 to 16.00
Local Coke Foundry, No. 2.....	14.75 to 15.25
Local Coke Foundry, No. 3.....	14.25 to 14.75
Local Scotch, No. 1.....	15.25 to 16.00
Ohio Strong Softeners, No. 1.....	17.00 to 17.50
Southern Silvery, according to Silicon.	15.65 to 16.00
Southern Coke, No. 1.....	15.15 to 15.40
Southern Coke, No. 2.....	14.40 to 14.65
Southern Coke, No. 3.....	13.90 to 14.15
Southern Coke, No. 1 Soft.....	15.15 to 15.40
Southern Coke, No. 2 Soft.....	14.40 to 14.65

PHILADELPHIA.—A very strong market is reported on all sides. Most of the business is for short deliveries, but something is being done for the first half of this year. Prices for the first mentioned are firm and at full or slightly higher figures, while for the longer dates the average is about 25 cents per ton less. There is considerable diversity in price, however. Some makers are disposed to take advantage of the scarcity to get a little more money out of needy buyers, while others appear satisfied to go along at unchanged prices. Sales have been on a fairly large scale and Foundry Iron is moving at unchanged prices. There is a scarcity of good Iron for prompt shipment and the tone of the market is decidedly strong, at figures within the following range for Philadelphia and nearby points, and 25c. to 50c. less for deliveries within a radius of 100 miles south or west: No. 1 X Foundry, \$15.75 to \$16; No. 2 X Foundry, \$15.25 to \$15.50, and No. 2 Plain, \$14.75 to \$15.

PITTSBURGH.—The Pig Iron market is as strong as it possibly could be, and it has been made stronger by the fact that some of the blast furnaces have been compelled to bank for two or three days at a time, owing to the scarcity of Coke. The situation as regards the supply of Coke is serious and it seems to be getting worse. Foundry Iron is scarce for prompt shipment and is bringing good prices. We quote Bessemer Iron in small lots at \$16.15 to \$16.25; No. 1 Foundry at \$15.50 to \$16, and No. 2 at \$15 to \$15.50, all f.o.b. Pittsburgh.

CINCINNATI.—The history of the past week's business in the Pig Iron market is almost an exact duplication of what has been recorded each succeeding week for the last six. Furnaces are well sold up for the first quarter of next year. This is especially the case in regard to No. 4 Foundry Iron. A very large tonnage has also been placed for the second quarter deliveries. There is to-day practically but one scale of prices, and this is essentially so in Southern Irons. The market is steady and extremely satisfactory, and bids fair to so continue for

some time. The scarcity of cars for Coke and Iron shipments is very exasperating, and the only ameliorating condition is that no favorites are being played. We quote f.o.b. Cincinnati:

Southern Coke, No. 1.....	to \$14.25
Southern Coke, No. 2.....	to 13.75
Southern Coke, No. 3.....	to 13.25
Southern Coke, No. 4.....	to 12.75
Southern Coke, No. 1 Soft.....	to 14.25
Southern Coke, No. 2 Soft.....	to 13.75
Southern Coke, Gray Forge.....	to 12.75
Southern Coke, Mottled.....	to 12.75
Ohio Silvery, No. 1.....	\$15.10 to 15.60
Ohio Silvery, No. 2.....	14.60 to 15.10
Lake Superior Coke, No. 1.....	15.10 to 15.60
Lake Superior Coke, No. 2.....	14.60 to 15.35
Lake Superior Coke, No. 3.....	14.10 to 14.85

ST. LOUIS.—The market for Pig Iron is still controlled by the same influences as last reported, and a large and satisfactory volume of sales and inquiries can be noted. Several furnaces are practically out of the market for the first half of 1902. We quote as follows for cash, f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$14.75 to \$15.00
Southern, No. 2 Foundry.....	14.00 to 14.25
Southern, No. 3 Foundry.....	13.50 to 13.75
Southern, No. 4 Foundry.....	13.00 to 13.25
No. 1 Soft.....	14.50 to 14.75
No. 2 Soft.....	14.00 to 14.50

THE HARDWARE TRADE.

The record made by the last month was, on the whole, very satisfactory. Not only was the volume of business good, but prices were, on the whole, quite well maintained. Weakness in a few lines which, owing to special reasons, developed lower prices is not to be taken as indicating the condition of the market as a whole, which is feeling constantly the effect of the large volume of trade and the strength in the price of the raw material. The condition of the iron market is such as to exert a steady influence on the values of the manufactured products. The matter of labor must not be overlooked as an element in the cost of goods. While there is no general advance in wages, in nearly all factories there has been a tendency in this direction, as individual advances have been made which, though not important in themselves, make in the aggregate a perceptible addition to the cost in producing the goods. The scarcity in several lines contributes to the general strength of the market and causes more or less inconvenience to the trade.

NOTES ON PRICES.

Wrought Iron Pipe.—The Wrought Iron Pipe situation continues unchanged and is likely to so continue, according to all reports, until March or April of next year. A small item in a New York daily of last Saturday gave a report from Pittsburgh to the effect that independent producers of Pipe and Tubing had made a cut of 5 per cent. below the prices of the National Tube Company on orders for immediate delivery. This report, on investigation, appears to be absolutely without foundation in fact. There is no independent mill in position to make a cut of 5 per cent. below the National Tube Company's prices for the reason that the entire product of the independent mills up to the first of the year is already sold at prices equal to those quoted by the National Tube Company. It is understood that none of the independent mills have any Pipe whatever that they can deliver promptly, and there is no likelihood of their having any surplus stock that will not be used on orders now in hand much before the latter part of January or the beginning of February. The consumption of Pipe is just as active to-day as it has been at any period during the past two years. There is still a scarcity of some sizes of Pipe, and with this condition there appears to be no reason for a decline in the mill prices. The mill price of Wrought Iron Pipe, according to good authorities in the trade, will not change before April or May, 1902. The reason given for this opinion is that the National Tube Company's product is sold up to that period, and all the sales have been made at prices which have been in effect since September of last year. The independent mills, it is argued, are not in a position to make prices, as none of the new mills having a sufficient ca-

capacity to seriously affect the National Tube Company will be in operation before April, 1902, and until the product of an independent concern having sufficient means and determination to force itself into a leading position is in the market and that concern is ready to take up the fight with the National Tube Company, the latter will continue masters of the situation.

Malleable Iron Fittings.—Under date of November 6, 1901, the manufacturers of Malleable Iron Fittings advanced the list price of Malleable Class A Iron Fittings 10 cents per pound. The list prices now are:

Malleable Fittings, Black, per pound.....40c.
Malleable Fittings, Galvanized, per pound.....50c.

These prices are subject to the regular discounts. The following is a list of Fittings comprised in Class A:

Elbows1/8, 1/4 x 1/8, 3/8 x 1/8 inch
Tees1/8, 1/8 x 1/4, 3/8 x 1/8 inch
R. & L. Couplings.....1/8 inch
Couplings, R. H.....1/8 inch
Ells, R. & L.....1/4 and 3/8 inch
R. & L. Return Bends.....3/8 and 1/2 inch

Nipples.—The Steam Goods supply houses notified the trade that Nipples longer than 6-inch are not kept in stock, but are cut to order only. Prices will be based on the price of Pipe, with charges for cutting and threading added. List prices of Extra Heavy Nipples will be three times the list of regular Nipples.

Asbestos Air Cell Coverings.—F. J. Gast, 26 Cortlandt street, New York, manufacturer of Asbestos Air Cell Coverings for hot air furnace pipe, furnaces, steam pipe, boilers, &c., quotes the following discounts from the list given below on the three classes of these Coverings which he is manufacturing:

	Discount.
Class A, 1 inch thick, for high pressure.....	50 %
Class B, 3/4 inch thick, for low pressure.....	60 %
Class C, 1/2 inch thick, for hot water.....	65 %

Inside diam- eter of Pipe.	Per lin. ft., canvas jacketed.	Elbows 90°—45°.	Tees. Valves.	Crosses.
1/2 inch.....	15c.	16c.	24c.	28c.
3/4 inch.....	16c.	20c.	26c.	34c.
1 inch.....	18c.	20c.	26c.	34c.
1 1/4 inch.....	20c.	20c.	26c.	34c.
1 1/2 inch.....	22c.	20c.	26c.	34c.
2 inch.....	24c.	22c.	29c.	38c.
2 1/2 inch.....	27c.	25c.	33c.	42c.
3 inch.....	30c.	29c.	38c.	48c.
3 1/2 inch.....	34c.	32c.	42c.	54c.
4 inch.....	38c.	35c.	47c.	60c.
4 1/2 inch.....	42c.	40c.	52c.	64c.
5 inch.....	46c.	46c.	60c.	72c.
6 inch.....	50c.	52c.	72c.	80c.
7 inch.....	55c.	66c.	96c.	88c.
8 inch.....	60c.	80c.	108c.	96c.
9 inch.....	65c.	88c.	120c.	108c.
10 inch.....	75c.	100c.	140c.	120c.
12 inch.....	90c.	140c.	175c.	150c.

Gast's Asbestos Air Cell Boiler Blocks and Boards are sold from the following list, which is subject to a discount of 50 per cent.:

	Per square foot.
1/2 inch thick.....	12c.
1 inch thick.....	24c.
1 1/2 inch thick.....	36c.
2 inch thick.....	48c.

His Asbestos Standard Cement is sold at \$4 per bag, and his Special at \$3 per bag, both subject to a discount of 50 per cent. Pipe Covering in the form of rolls 1/4 inch thick, 36 inches wide, and containing 250 square feet, for furnacemen and others, is sold at \$10 per roll, subject to a discount of 50 per cent.

Stove Pipe.—The advent of a cold snap has stimulated the demand for Stove Pipe to a marked extent. Orders for Stove Pipe have been coming in from all quarters throughout the week and dealers in this class of goods are seeing their stocks rapidly becoming depleted. Prices are firm, but no higher than for some time past.

Wire Nails.—While the volume of Wire Nails required to supply the demands of the trade is large, buyers are placing orders on a conservative scale. It is evident that competition is having a weakening effect upon the mar-

ket and concessions are being made of from 10 to 15 cents per keg in some cases. At the same time a large amount of business is being done at the regular quotations. The demand for Wire Nails in New York continues at about the average of the last few weeks. The market is rather weak for small lots at store, at \$2.45 to \$2.50 per keg.

Cut Nails.—The Cut Nail Manufacturers' Association, at a meeting held last week, reaffirmed former prices for the month of November. The tone of the local Cut Nail market remains unchanged. Steel Cut Nails are still scarce. Small lots from store are quoted at \$2.18 to \$2.30 per keg.

Wire.—A good seasonable demand for Wire continues, and it is heavier than usual at this time of year. There is some shading in the price of Plain Wire for good orders and for certain points of shipment. Plain Wire in small lots at New York is quoted at 2.00 cents, and Galvanized at 3 cents.

Window Glass.—Representatives of the Window Glass combines and the Executive Committee of the National Window Glass Jobbers' Association recently held a meeting at which the manufacturers agreed to sell members of the association small Glass at a considerable reduction from former prices. This action was foreshadowed by the arrangement, to which we referred last week, by which the members of the Jobbers' Association were permitted to use their discretion in making prices low enough to meet foreign competition. Local quotations are unchanged, at 80 and 20 per cent. discount for less than car lots from store.

White Lead.—The market for White Lead in Oil is reported to be in a somewhat demoralized condition, owing to the cutting of prices in the West having spread to the East. Concessions from regular quotations of from 1/4 to 1/2 cent per pound on some brands are said to be obtainable. White Lead in Oil is quoted here in a retail way at 7 to 7 1/4 cents per pound.

Linseed Oil.—During the week out of town Raw Oil dropped in price, causing the price of City Raw with those concerns who have Oil to be reduced from 4 to 5 cents per gallon. Others who have little Oil to dispose of, however, still continue to quote at last week's figures. Thus, the current range of prices is wide. City Raw Oil in moderate sized lots is now quoted at from 62 to 66 cents per gallon. The demand is quite active for small lots. On a declining market it is not expected that more than enough Oil to supply urgent requirements will be purchased.

Spirits Turpentine.—The market for Turpentine has not gained in strength during the week. The local demand has been restricted to small lots. This light demand, with a somewhat easier feeling in the Southern market, has caused a falling off in price of 1/2 cent per gallon. Retail quotations are now 38 1/2 to 39 cents per gallon.

Lawn Mowers.—Manufacturers of Lawn Mowers are sending out their price-lists for next season, which are practically the same as those ruling this year.

Manila Rope.—A further advance of 1 cent in Manila Rope was made this week, making the basis 13 cents a pound.

Window and Door Screens.—The manufacturers of Window and Door Screens have announced their prices for next spring. They show little or no variation from those prevailing in the past season.

American Exhibition, Crystal Palace, London.

Preparatory work is now being done for an American Exhibition, to be held in the Crystal Palace, London, England, May to September, 1902. It will be distinctly American, and is designed to demonstrate the immense commercial development which has taken place in the United States during recent years in American products, arts, industries and inventions. The time chosen will enable intending exhibitors to get their products before

probably the greatest assemblage of visitors from the English colonies from all over the world ever gathered in London, the magnet being King Edward's coronation ceremonies, which will occur in June next. The Advisory Committee contains the names of many well-known men, both English and American, including the Lord Mayor of London. The Commissioner for the United States is Alfred H. Post of the Anglo-Saxon Shipping Company, Produce Exchange Building, New York, from whom plans and particulars concerning space can be obtained. The Crystal Palace contains 150,000 square feet of space for exhibits, there being 200 acres of ground in all, of which the building covers 16 acres.

Corrugated Galvanized Iron and Steel Duty.

The United States Treasury Department has made the following ruling on a case submitted by the Collector of Customs at San Juan, P. R.:

"The Department duly received your letter, dated June 11 last, concerning an apparent conflict between the decision of the Department, dated April 1, 1901 (T. D. 22,929), and an unpublished decision of the Board of United States General Appraisers, in a case which arose at your port, concerning the classification of corrugated galvanized iron sheets, valued at more than 3 cents per pound.

"The Department is in receipt from the Board of a copy of the decision in the matter of the protest of Palacios & Co., referred to by you, from which it appears that the merchandise was assessed for duty at 12-10 cents per pound under paragraph 135, and two-tenths of 1 cent per pound additional in accordance with the provisions of paragraph 132 of the tariff act of July 24, 1897. The importers claimed that the same was properly dutiable at the rates provided in paragraphs 131 and 132, respectively, of said act.

"It is manifest that, as the sheets were valued at more than 3 cents per pound, they were excluded from classification under said paragraph 131, which provides for sheets of similar character, 'valued at 3 cents per pound or less,' and the Board so held in overruling the protest and affirming the assessment of duty.

"The merchandise in the case was entered on June 22, 1900, a date long anterior to the date of the Department's decision above alluded to, although the decision of the Board was rendered May 28, 1901.

"You are, therefore, hereby instructed to assess duty on galvanized iron sheets, corrugated or crimped, when valued at more than 3 cents per pound, at 45 per cent. ad valorem under paragraph 193, and at two-tenths of 1 cent per pound additional for galvanizing under paragraph 132 of the existing tariff act, while on similar sheets of steel duty must be assessed under the provisions of paragraph 135, and likewise the additional duty in accordance with paragraph 132 of said act, under the Department's decision (T. D. 22,929, dated April 1, 1901)."

The officials of the Canadian Pacific Railway have at present under consideration an immense scheme for the irrigation of the northwest of Canada, by which it is proposed to make good farming and grazing country out of the millions of acres which are dry and arid between Calgary and Medicine Hat, on the North Railway line. James Anderson, one of the leading irrigation engineers of the world, has recently traversed this area, and reports that there is nothing to prevent this work being successfully carried out. His report is being considered by the Canadian Pacific authorities, and it is understood that, as an experiment, 300,000 of the 3,000,000 barren acres will be put under irrigation.

S. W. Hanauer, United States Deputy Consul-General at Frankfort on the Main, reports that Germany's importations of iron ore during the first six months of this year were 2,048,020 metric tons, valued at 37,500,000 marks, about \$8,750,000. Spain furnished 54.6 per cent.; next came Sweden with 25.8 per cent.; Austria-Hungary supplied 6 per cent.; Belgium, 4.9 per cent.; Algiers, 2.9 per cent. Now that ocean freights are low, Mr. Hanauer

suggests that we ought to be able to supply Germany with iron ore.

The Pullman Palace Car Company are building a very handsome private car for Charles M. Schwab, president of the United States Steel Corporation. The car will be ready in a short time and will be named for Mr. Schwab's wife.

PERFORATED METALS

STEEL, IRON, COPPER, ZINC, BRASS, TIN, and all other metals
PERFORATED AS REQUIRED for

Grain Cleaning and Mining Machinery, Woolen, Cotton, Paper and Pulp Mills, Rice, Flour and Cotton Seed Oil Mills, Sugar and Malt Houses, Distilleries, Filter Presses, Stone, Coal and Ore Screens, Brick and Tile Works, Filters, Spark Arresters, Gas and Water Works, Oil, Gas and Vapor Stoves, Coffee Machinery, &c., &c.

Standard Sizes Perforated Tin and Brass Always in Stock.

The Harrington & King Perforating Co.,

Eastern Office, 234 Pearl St., NEW YORK.

217 North Union St., CHICAGO, ILLS., U.S.A.

Sheet Metal Pattern Drafting

A course of instruction by mail for tinsmiths, coppersmiths, plumbers, sheet-iron workers, furnace workers, skylight makers and others that will enable a student to "strike out" working patterns for all kinds of sheet metal work. This is what a student says:

His Course More Than Paid for Itself

I am a tinsmith, and consider your course in Sheet Metal Pattern Drafting one of the best investments I ever made. Before I was half through I had realized from it more than the money paid for the whole course.

M. E. TOBIAS, Jr.
63 Fifteenth St.,

The Roofing, Cornice

And Skylight Manual

175 Pages, 170 Illustrations, 13 Plates

THE ROOFING, CORNICE AND SKYLIGHT MANUAL is an important addition to our increasing line of practical books for Sheet Metal Workers. It is a substantial volume, well printed and bound, and freely illustrated with engravings, accurately showing the various phases of work in progress.

The three subjects of Tin Roofing, Cornice Shop Practice, and Skylight Construction are discussed in a thorough and practical manner, the work being designed as a shop companion or reference for sheet metal workers, as well as a guide to young mechanics who are intending to follow any or all of these branches of work.

Tin Roofing Pages 1-50. This section presents an article prepared specially for the book by an expert mechanic. A few of the subjects treated are the laying of flat and standing seam roofing, described in detail, with instructions for flashing around chimneys; connecting roofs with wall flashing; covering parapet walls and bulkheads; putting in valleys; shingle flashing, &c. An important table is given for finding the quantity of tin required for roofs.

Cornice Making Pages 51-140. This part of the volume consists of an article entitled "The Country Cornice Shop," reprinted from *The Metal Worker*, and treating the subject at length. It embraces a description of a shop equipment, such as can be purchased or made, and adapted to the country shop. A few of the subjects treated are the method of developing the patterns for much of the simpler work, as well as for cutting cornice miters; attaching molded gutters to brick walls; the attachment of eave trough to roofs of different kinds; the manufacture of round and square leaders; the making of simpler ornaments, etc.

Skylight Construction Pages 143-175. This division of the work consists of two prize essays reprinted from *The Metal Worker*, giving instructions for the production of skylights of all sizes, the development of hip bar and miters, also curb and side bars. One of these articles describes a skylight without a ventilator, and the other a skylight with a ventilator in the top. The illustrations cover various phases of the work fully and also show the method of catching the condensation which occurs with all skylights.

A UNIVERSAL REMEDY FOR LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 800 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails. In 5, 10 and 15 lb. Pails.

Special Discount to Jobbers and Large Buyers.

Galvanizing and Tinning.

A Practical Treatise on Coating with Tin and Zinc, with a Special Chapter on Tinning Gray Iron Castings. By W. T. Flanders. Size 5½ x 8 inches. 93 pages, 40 illustrations. Cloth bound. Price \$2.00.

The author of this work has made a specialty of galvanizing and tinning, and has been employed to erect plants in various parts of the country, also to instruct the owners, so that, in all instances, they have been able to operate them successfully. The subject of galvanizing is, therefore, treated from the standpoint of an expert and in a practical manner. The selection of materials and apparatus for erecting plants of large and small capacity is treated, together with instructions for their equipment and accompanied by many illustrations of the plants and of the tools and appliances. Plain directions are given for the preparatory treatment of metals and articles to be coated, and every detail which is of importance in successfully applying to metals a secure and attractive coating is described. The tinning of articles is treated in the same practical manner. The difficulties found by many who have attempted to tin malleable and gray iron castings are explained and methods for doing the work made simple.

CONTENTS.

Galvanizing.

Locating a Plant and Selecting a Kettle.
The Galvanizing Room.
Tanks for Acids and Other Purposes.
Tools for Galvanizing.
Filling and Firing a New Kettle.
The Use of a Pyrometer.
Materials Used in Galvanizing.

ART IN METAL CEILINGS

Roman Design.

Roman ideas of architecture and design were largely borrowed or developed from the Greek.
Hence, in many respects, there is more or less of a similarity in the style of these two periods.
Roman, however, is the bolder, more massive and more elaborate of the two.
Our Roman design of

BERGER'S
Classik
TRADE MARK
METAL CEILINGS

is well suited for use in Public Buildings, Halls and other places where a deep paneled or heavy girder effect is desired.
Write for particulars of this and other noted styles we manufacture.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting
as applied to all branches
of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection
of 218 problems and an elaborate
explanation of the principles of
pattern cutting, including Triangu-
lation.

It embodies the problems of the
former Metal Worker Pattern Book,
all of which have been revised, and
many of which have been entirely
rewritten and solved by more ap-
proved methods. To these have
been added 75 new problems and
much other new material and ex-
planatory matter, making this work
a model of completeness in every
respect.

ARRANGEMENT.

In point of arrangement the new
work far surpasses the former one
in that the problems are classified
under three different heads, and
simply indexed, and also that by
means of a table of contents any
required department of the work
can be easily found.

CONTENTS.

While Chapter VI, comprising the
greater part of the work, is devoted
to the solution of problems, the
five preceding chapters thoroughly
explain the principles of pattern
cutting, and place the student in
possession of the preliminary infor-
mation necessary to a thorough
understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tinnerns, Cornice Makers and
Sheet Metal Workers should be
provided with a copy of

The New Metal Worker Pattern Book.

Price \$5, post or expressage paid.

THE DOUBLE TRUSS CORNICE BRAKE.

This is the most practical brake on the market.

It is the most practical because, in the first place, it is lower in price than any other Cornice brake that will do perfect work. Secondly, because its practical construction enables you to use it to the most profitable advantage.

When you hear about a good thing in your line of business, investigate it. Turn on it the light of reason and consider its money-making possibilities.

Let us send you information regarding our double edge on front leaf, for making finemembers and corrugations.

The Double Truss Cornice Brake Co.,

**1453 Niagara St.,
BUFFALO, N. Y.**

Ask us about our new Electric City Gutter Former. It will do as good and as quick work as any other machine used for a like purpose and can be sold for 50% less.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No 12 gauge, cut wire or bar-steel $\frac{1}{8}$ inch thick, cut off and mitre angle iron $\frac{1}{8}$ inch thick, and do it perfectly.

PRICE, - - \$35.00.

PARAGON POINTS—ALL TOGETHER.

The furnace that you want to handle is the furnace that has the fewest joints, the furnace with the equalized draft—the largest radiating surface—the ball bearing grate—the furnace that is self cleaning and that is most adaptable to your needs—and that furnace is the Paragon. It is well named—and it costs no more than the ordinary furnace.

ROUND OAK- STANDARD of AMERICA

One of the best
points of the
famous Genuine
Round Oak
is the way

It heats the
floor under
and around

the stove.

The base is small.
The grate hangs
low in the ash pit,
close to the floor—
no ash pan in the
way of the heat.
See? Notice the
imitations—
very large square
bases, grate high
from the floor,
deep ash pan.
How can they
warm the floor?
This is but one
of a great many
reasons why the
Round Oak outsells
all other stoves.
We want an agent
in every town—
where we have
none.

Finest Factory in this Line in the World.

READ OUR OFFERINGS.

Special Advantages Over All Other Heaters.

OUR HEATERS are only 4 ft. 3 in. high, giving excellent elevation for Hot Air Pipes.

OUR HEATERS ARE ALL CAST IRON, no repairing of sheet iron drums necessary every few years.

OUR MANIFOLD TUBES are steel, $\frac{1}{8}$ inch thick, and will wear for a lifetime.

OUR HEATERS are supplied with the most modern grates, perfect dumping and shaking. Each bar can be separately replaced.

OUR HEATERS are so arranged that they can be perfectly cleaned by any one, and in a few moments.

Equally Efficient with Hard or Soft Coal.

Our Heaters save the heat others waste up the chimney and send it through the house, therefore reduce coal bills.

Bergstrom Bros & Co.

NEENAH, WIS.

The Stanton Seamless Heater,

PORTABLE CASED.

STATE COLLEGE, PA., June 15, 1900.

THE STANTON HEATER CO., Martin's Ferry, Ohio.

GENTLEMEN:—The Stanton Heater is giving the best kind of satisfaction. It will produce good heat from any kind of fuel. My average cost of fuel, per month, for the past winter was three tons of coal dust from soft coal to heat 43,000 cubic feet of space with a No. 68 Heater; however, this space is 3,000 cubic feet over the capacity of your Heater, but the heater did the work easy, and held the temperature in zero weather so it would not change over four degrees in twelve hours without touching the Heater.

The Stanton Heater is, in my judgment, the most modern and economical warm-air generator of this age.

Sincerely yours, J. N. KRUMRINE.

DIGHTON FURNACE Co., Taunton, Mass.

DEAR SIRs :—I have your kind letter of the 17th and beg to say that your Furnaces are now running **VERY SATISFACTORILY**, but we have had no cold weather yet, and I believe a testimonial from me a little later would be worth more to you than it would now, for I could then state that I had waited until our severest weather in order to give your work thorough test.

I have no doubt that they will come fully up to every claim you have made, but a testimonial, to be worth anything, should state what these Furnaces would do when put to the test.

Assuring you of my best wishes, I am,

W. T. MELTON.

WOOD FURNACES.

OUR IMPROVED MONITOR.

The most powerful heater made.

2 SIZES, PORTABLE OR BRICK SET.

No. 88 for 8 ft. wood. No. 50 for 4 ft. wood.

OUR LOW PRICED HOT BLAST.

The most practical, durable heater on the market at anywhere near its cost.

FIRE BOX BODY made in one piece, corrugated. Is very heavy and cannot break or warp.

RADIATOR with heavy cast iron heads, heavy plate iron shell and hot air flues, has extra large radiating surface and is self cleaning. Every part of radiating surface is directly exposed to fire, allowing no possibility of creosote in the apparatus. No wood grate. Fuel burns on the ashes in the only practical, economical way.

3 SIZES, PORTABLE OR BRICK SET.

Nos. 36, 42 and 48, for 3, 3½ and 4 ft. wood.

Thousands in use in all sections of the country. Testimonials and full particulars sent on application to the manufacturers.

THE HOT BLAST.

Established 1899.

Incorporated 1894.

WOOD & BISHOP CO., BANGOR, MAINE.

KINEO FURNACES
FOR WOOD.

The Kineo Furnaces are built to secure durability and heating qualities. The smoke enters the radiators on the back and passes entirely around the radiator before entering the chimney, making them the most powerful heaters known. Also manufactured in two sizes with steel radiators.

BRIEN HEATER CO.,
HOOSICK FALLS, N. Y.

Furnace Heating.

A Practical and Comprehensive Treatise on Warming Buildings with Hot Air, by William G. Snow, with an Appendix on Furnace Fittings. 170 pages; size, 6 x 9 inches. Cloth bound. Price, \$1.50.

This is the only book that has been brought out which presents a systematic and reliable treatment of the warm air furnace system of heating.

It deals with the various types of furnaces, their construction, proper location and setting, together with furnace fittings, and all matters pertaining to the installation of furnaces and to effective and economical heating by warm air. The subject is discussed for the first time by a competent author possessed of a scientific education and a practical training, who presents positive rules, based on a long experience, for guidance in designing furnace systems for dwellings and other buildings where this popular method is employed. The various details of furnace work are described simply and at such length that the volume will be valuable to all who are in any way interested in the subject. It is recommended to practical furnacemen, to architects, builders and house owners, and to tinnery and plumbers in suburban sections who do furnace work. To all these it will prove a reliable text-book and guide.

PARTIAL SUMMARY OF CONTENTS
BY CHAPTERS.

Chapter I.—Furnaces—Is devoted to Furnace Construction—The Relative Proportion of Furnace Parts—Secondary Heating Surface—Economy and Efficiency—Heating Capacity and Exposed Wall Surface—Manufacturers' Ratings of Their Own Productions, etc.

Chapter II.—House Heating—Compares Furnaces and other apparatus, and describes Method of Setting Brick and Portable Furnaces—Location and Area of Cold Air Supply—Cold Air Rooms and Air Filters—Return Ducts and Air Circulation—Size of Hot Air Pipes—Location of Registers, etc.

Chapter III.—The Combination System—Discusses Heating Distant Rooms with Radiators—Balancing the System—Location of Water Heater in Furnace—Capacity of Water Heaters—Size of Radiators, etc.

Chapter IV.—Air—Deals with the Necessity of Ventilation—Water Needed to Moisten Air—Expansion of Air—Velocity of Air in Tubes, etc.

Chapter V.—Heating and Ventilation of Buildings—Considers the Size of Furnaces Required—Fresh Air Room and Supply—Air Circulation—Size of Flues—Use of Stack Heaters—Size of Heating Coils in Vent Flues, etc.

Chapter VI.—Heating of Public Buildings, Churches and Stores—Is given to the Size of Furnaces Required—Grate Surface in Ventilated Buildings—Air Supply—Size of Heating and Ventilating Flues—Size of Stack Heater, etc.

Chapter VII.—Fan-Furnace Combination System—Is devoted to Positive Warm Currents from Fan Systems—Location of Fan and Driving Apparatus—How Good Furnaces are Aided by Fans—Types and Efficiency of Fans—Area of Ducts and Flues, etc.

Chapter VIII.—Temperature Control.

Chapter IX.—Estimate and Contract Blanks.

Chapter X.—Value of Fuels. The Proper Size for Furnace Chimneys—with tables.

APPENDIX.

Furnace Fittings—A section of 45 pages dealing with the Making of Furnace Casings—Metal Cold Air Boxes—Making Furnace Bonnets and Collars—Making Pipe and Elbows—Register Boxes and Stack Shoes, etc.

SENT, POSTPAID, ON RECEIPT OF PRICE, \$1.50

DAVID WILLIAMS COMPANY,
PUBLISHERS,

232-238 William St., New York.

A Tea-Kettle Boils Quicker on my Chimney than on my Stove.

IS IT SO?

It is said that a tea-kettle will boil quickest on top of a chimney. However that may be, all agree that there is too much heat wasted there. Nothing but the cross tube **ROCHESTER RADIATOR** has ever trapped it. If you were to heat a poker, would you hold it at the side of the flame or over the top? Or would you cook food on the side of a cook-stove in preference to the top? It is thus with the **ROCHESTER RADIATOR**, which takes the heat from the top of the current and not from the side. The cross tubes cool the hot current, just as you would blow across a cup of tea to cool it, only there are from 96 to 120 such currents in operation.

4,866 sq. ins.

ABOUT ESTIMATE BOOKS

For Plumbers and
Heating Men

Your Contract and Estimate Record Book for Plumbers is one of the best books that ever came into our house and we would not be without it for three times the amount it cost. We can figure without omitting anything with accuracy at a very short time. We think that every plumber should not be without this valuable book.

W. C. BENNETT & CO., Haverhill, Mass.

We have used an estimate book for three years and could not do without one. Would say that yours is far superior to any yet used and can cheerfully recommend it.

W. R. PARK & SON, Taunton, Mass.

A great advantage. Prevents the leaving out of small items, which amount to more than the cost of the book in a very short time.

CHAS. W. COOMBS, Lawrence, Mass.

Your Contract and Estimate Record Book has been of great use to me in both the saving of money and labor, and I would highly recommend it to any or all master plumbers.

THOMAS P. DOHERTY, Taunton, Mass.

These testimonials are a few of many, and indicate both that a well arranged estimate book, which provides complete lists of items to be figured upon, is a time, labor and money saver, and that the "CONTRACT AND ESTIMATE RECORD BOOKS" come up to this requirement.

THE EDITIONS ARE AS FOLLOWS:

CONTRACT AND ESTIMATE RECORD BOOK FOR PLUMBERS

OFFICE EDITION.

200 Pages. Arranged for 100 Estimates.
Size 8 x 11 inches. Cloth bound, \$1.50

Strained Relations in the Plumbing Trade.

The report which we give on another page of the meeting in Chicago of the National Committee of the Confederated Supply Associations on Wednesday and Thursday will command attention, relating as it does to efforts which have been made in many different forms to regulate and control the sale of plumbing goods so as to serve the interests of the trade immediately concerned. Our readers will recall that there was an interruption of the fairly harmonious relations which existed between the National Association of Master Plumbers and the Confederated Supply Associations when in September last the revised New York Conference Resolutions were abrogated by the association of the master plumbers on account of the failure of the arbitration provisions. The strained relations which thus culminated were an important subject for consideration by the meeting of the committee of the Confederated Supply Associations which has just been held. It is evident, however, that there has been no improvement in the situation so far as harmony of action is concerned, and the two bodies, both of much weight and influence, are even further apart. Possibly this may ultimately result in the finding of some line on which they can work harmoniously. Of the way in which this is to be accomplished there is, however, no immediate indication. The refusal of the Confederated Supply Associations to adopt the Cleveland Resolutions of the master plumbers and preferring instead to lay down a new platform in what will be known as the Chicago Resolutions seems, indeed, to widen the breach.

So far as manufacturers and jobbers are concerned there is little doubt that the action taken at Chicago will meet with general approval and not a little satisfaction, as the important trades represented thus take a more reasonable and tenable position in regard to the marketing of goods. Many, even if they have not always expressed the conviction openly, have realized that in order to satisfy the demands of master plumbers the manufacturers granted them far too much in the New York Conference Resolutions. In view of the radical and arbitrary demands made at that time this was necessary, if any basis for united action was to be found. The new resolutions have receded, it will be seen, from many of the restrictions on trade which were laid down in the old ones, while at the same time they

seem to give to plumbing interests all the protection that is requisite or desirable, and aim to limit trade to as narrow lines as are either reasonable or practicable.

The resolutions just passed seem to make all necessary and equitable restriction and to leave the way open for liberty of action on the part of manufacturers and merchants, which is fair to the contracting plumbing trade and their possible customers. The letter sent by the meeting to the president of the association of master plumbers is commendable in its spirit and in the stand taken in favor of trade protection and the arbitration of all trade difficulties. With the evident difference of opinion between the two bodies there is, indeed, an opportunity for strife in the trade, which will be productive of little good and might result in serious injury to interests which have been heretofore carefully conserved. It is a matter for congratulation that the prospect is that business in these lines is to be less trammelled than of late by restrictions which were so stringent that they became impracticable. A broader policy, such as is suggested by the action taken at Chicago, especially when accepted by the whole trade, will be attended with many advantages and tend to promote the general welfare.

The Copper Situation.

Interest in the copper situation still continues acute. While the leading copper interests maintain their prices stiffly and intimate that they do not propose to recede from their present position, the impression is growing more general that it will be impossible for them to hold the present high prices very much longer unless they decide upon a radical restriction in the output of their mines during the coming months. Even then, it is claimed, the Amalgamated Copper Company would find it difficult to maintain the present level of prices, in view of the fact that the independent companies are probably sufficiently strong to break prices, should they decide upon such a course. There are not wanting those who predict that the Amalgamated Copper Company may conclude to announce a sudden reduction in price, which will be so radical as to eliminate all competition on the part of the outside producers. It seems that some change must occur before very long. All the available statistics point to the conclusion that stocks of copper in first hands must be accumulating rapidly. Exports of the metal during the past few months have fallen off materially, as compared with the exports of the past few years, while a considerable amount of foreign copper has been imported into this country lately by consumers, who have been able to buy the metal abroad and land it here at a lower cost than they could purchase the domestic article. The consumption of copper in the United States does not appear to have exceeded that of last year or the year before, while the production has kept up to the same level. Consequently, there must be a big surplus laid up somewhere. It is this that induces the consumers of copper to confine their purchases to such amounts as are necessary for the filling of their current needs. The market for copper is a waiting one and the whole metal trade is look-

ing out for developments in this department. The cut of $1\frac{3}{4}$ cents in the price of copper wire, made this week by one of the leading manufacturers, is significant as suggesting a lack of confidence in the continuance of the present prices of raw material.

A Strong Iron Market.

The monthly blast furnace statistics published by *The Iron Age* show that the month of October was a record breaker in the production of pig iron. The output of the furnaces reached the great total of 1,400,000 tons, or at the rate of 16,800,000 tons per annum. The furnaces in blast on November 1 had a weekly capacity of 320,824 tons, based on their actual yield in October. This is an increase of nearly 13,000 tons over October 1 and is in excess of any previous record, the next highest being 314,505 tons for June 1 last. Notwithstanding the augmented output, the stocks of iron at the furnaces showed a decline from 351,593 tons on October 1 to 273,251 tons on November 1. This is the heaviest reduction in stocks made in a single month in a long period. That it was made concurrently with a great increase in production is a strong illustration of the remarkable activity now prevailing in the iron trade, and tends to strengthen the opinion that prices are not likely soon to recede. It is, in fact, well for consumers that the control of the market is in strong hands, as a little injection of the speculative element could easily send pig iron values considerably higher. The situation, moreover, promises to be further strengthened in November by the great difficulty still experienced by the furnaces in securing a sufficient supply of coke, owing to the serious shortage of cars. Many furnaces have been banked for this reason, and the production for this month will be curtailed to a considerable extent. This will affect the whole market for finished iron, but particularly the output of steel, the supply of which was not equal to the demand when everything was running smoothly in October.

The Higher Cost of Living.

According to *Dun's Review*, the cost of living has reached the highest point in ten years, and is 7 per cent. higher than at this time last year. This increase in the cost of commodities which go to make up the necessities of life has taken place notwithstanding the cheapening of many manufactured goods through improved processes and the absence of undue inflation in any class of goods. No artificial stimulus is responsible for the present high level of manufactured products. Aside from a rise in food products, due to short crops, the present condition of high prices is attributed entirely to prosperous business conditions and the full employment of labor at high wages. Prior to November 1 the maximum of values during the past ten years was reached in March, 1900, when the cost of living per capita per annum was \$97.40. The figure now is \$97.74, or 34 cents higher. This has been caused in large measure by exceptionally high prices for cereals and breadstuffs. Dairy and garden products also rule higher, as well as many miscellaneous commodities, but clothing is considerably cheaper. The cost of the necessities of life naturally tends to advance in proportion to the ability of the people to consume. Fictitious values sometimes prevail, but these are usually of short duration and are generally eclipsed by the preponderance of normal conditions in the general market. Under the circumstances it is fortunate that industries are flourishing and that full employment is provided for the large bulk

of the wage earning population; otherwise the greater cost of living would be likely to bring considerable distress to the class referred to during the coming winter. Meanwhile the average citizen has discovered that it costs more to live than it did a year or two back. He finds it increasingly difficult to fill the market basket, pay his rent and meet the necessary expenses of his family on the same income that sufficed for all his needs in past years, for it is not in evidence that wages generally have risen in proportion with the higher cost of living.

Cheaper Fuel.

In view of the wonderful natural resources recently opened up in the Texas oil fields one need not be a prophet or the son of a prophet to foresee a remarkable industrial development of the entire South and Southwest in the coming years. The use of oil as a substitute for coal in the production of steam for power purposes has already received a decided impetus from the discovery of what appears to be a practically unlimited supply of petroleum in a region in which manufacturing and other industries have been handicapped hitherto by the high cost of coal and wood used for fuel. Railroads and other large users of steam power in territory within ready reach of the new oil fields are expending or preparing to expend large sums in the building of boilers upon plans especially designed for the use of oil or are altering existing boilers so that they can be utilized for the liquid fuel, and many of the smaller users of power are preparing to adopt the cheaper and more readily obtainable fuel. It is easy to see what an important bearing this revolution in fuel is likely to have upon the industrial future of the sections lying within a reasonable distance of the oil fields. But the wider adoption of oil fuel, not only for power but also for heating purposes, is not likely to be confined to the territory referred to. When the pipe lines are completed from the oil fields to the Gulf ports the producers will be able to ship the oil by water and lay it down at any of the Atlantic ports at a cost far below that of coal. Under the circumstances it is not unreasonable to expect not only an era of cheaper fuel, but also other changes which may have important significance in industrial matters.

The Metric System Again.

United States Consul Skinner, at Marseilles, France, records an incident which occurred under his observation not long ago, as illustrating the desirability of the adoption of the metric system in the United States, which, except Great Britain, is the only important manufacturing nation still employing the old system of measurements and weights. The United States naval collier "Scindia" arrived at Marseilles with her boiler tubes burnt out, and under urgent orders to proceed to Manila. The vessel went to the French port, as it was considered the place best equipped to make the absolutely essential repairs. Every facility was offered for the prompt refitting of the boilers by local contractors, but it was found that all the tubing in the city had been manufactured in France, and according to metric dimensions, and none of it could be utilized in the "Scindia's" boilers without forcing the shells. There was the variation of a hair's breadth in the dimensions, but it was sufficient to prevent the work from being accomplished, and orders had to be cabled to the United States for material, which was sent over in one of the German steamers—probably at express rates—and delivered at Naples, where the repairs were eventually carried out. The

ship was delayed two or three weeks, in consequence of the fact that her boilers had been built upon a scale of feet and inches, while European tubing was manufactured according to the metric system. This is another example of the disadvantage at which American manufacturers and their British *confrères* are placed abroad by their continued adherence to British standards of weight and measurement.

Ventilating a Tunnel.

For a long time passengers arriving at the Grand Central Depot in New York City have endured no small amount of annoyance from the foul air in the tunnel through which the trains enter the city. This annoyance has often been brought to the attention of the authorities, and the Board of Health, after discussing the problem with the engineers of the railroad company, at length have taken steps with a view to removing the cause of complaint. A good start has now been made in the transformation of the hot, gaseous, smoke laden Park avenue tunnel into a well ventilated subway. The problem has received the attention of skillful engineers, and it is hoped that their efforts will be crowned with even greater success than they anticipate. A more difficult problem than that under consideration has seldom been brought to the attention of the ventilating engineer, nor is the particular work necessary with such a problem often engaged in under conditions which require so much skill and care on the part of the workmen. The tunnel is being used by the trains all the time, and the space allotted to the workmen is naturally restricted. The task, however, is said to be progressing satisfactorily, and the engineers are confident that eventually there will be ample opportunity for fresh air to enter the tunnel and the foul air to be removed.

A marked increase is noted in the shipments of American anthracite coal to Europe during the past few months. Curtailment of the European supply, owing to labor troubles in the Welsh and French coal fields, has stimulated the Continental demand for American hard coal, particularly in Germany, and low ocean freight rates, with comparatively light grain exports from this country, have enabled the American anthracite coal interests to take advantage of the situation and secure some good sized orders for their product. It is understood that the British hard coal interests are not inclined to dispute the Continental markets with the American producers, as the Welsh supply of hard coal is limited and is little more than sufficient for domestic manufacturing purposes. Consequently a promising field seems to be opening up for the marketing of the surplus product of the American anthracite mines.

At a meeting of the trustees of the Carnegie Institute of Pittsburgh on Tuesday Andrew Carnegie announced his decision to add \$2,000,000 more to the already large gifts he has made to that institution and to the new polytechnical school to be established in Pittsburgh through his munificence. He will increase the endowment fund of the proposed school by \$1,000,000, making it \$2,000,000. This will give the school an annual revenue of \$100,000, which Mr. Carnegie thinks is enough for it to start with. An additional endowment of \$1,000,000 has also been made by Mr. Carnegie to the Carnegie Institute, making a total of \$6,000,000 given to that establishment. The original appropriation made for the proposed Carnegie Technical School was conditioned upon the provision by the city of a suitable site. This condition has been filled in the purchase by the city of 11 acres of land at the south entrance to Schenley Park, adjoining the Carnegie Institute. The erection of the necessary buildings upon this site will be begun at

an early date. The buildings will follow the design of the Worcester Technical School of Worcester, Mass., and the general plan of that institution will be followed in the Pittsburgh school. Mr. Carnegie has given *carte blanche* in the erection and equipment of the necessary buildings, without naming any specific sum. This last benefaction will bring Mr. Carnegie's gifts to the city of Pittsburgh up to \$15,000,000.

THE NEW AUSTRALIAN TARIFF.

The Australian mail, received this week, brought the details of the new tariff introduced by the Australian Federal Government, which went into effect on Tuesday, October 8. The new tariff institutes ad valorem duties ranging from 15 to 25 per cent., and in many instances a specific duty representing a broader measure of taxation. So far as the interests of the United States are concerned, and as significant of the feeling of the Australian Commonwealth, it is gratifying to observe that there are no provisions giving preference to English goods, but that the tariff applies impartially to importations from whatever source of sale or manufacture. The United States thus has an opportunity to cultivate the Australian market on equal terms with all other countries. The importance of the Australian trade to this country is indicated in the fact that last year it amounted to \$20,000,000. The new scale of duties will be collected from October 8, and for any items that may eventually fail to pass the legislature, or which are reduced, a rebate may be claimed. In the event of higher schedules being adopted, if any are made, no additional payment of duty will be required.

GALVANIZED IRON.

Among the articles on which duties have been imposed are plain galvanized iron sheets or plates, which are taxed at 15 shillings per ton, and corrugated galvanized iron at 30 shillings per ton. Hitherto these materials have been admitted free in New South Wales and Victoria. South Australia has had a duty of 30 shillings a ton on corrugated galvanized iron, and Queensland has had a duty of 40 shillings. Now, with the one Australian market, this duty is considered sufficient to justify the erection of galvanized and corrugating plants in Australia, since black sheets are admitted duty free. Australia is, perhaps, the world's best market for galvanized corrugated iron, as the majority of country houses, small villas, farms, &c., are roofed with it.

In connection with the duty on galvanized iron the new tariff bill provides that so soon as the manufacture of this material has been sufficiently established in the Commonwealth, a duty may be attached by proclamation of 10 per cent. ad valorem on plain galvanized iron and 15 per cent. on corrugated.

Among other dutiable articles named in the new tariff are sheet lead and lead pipe, on which there is a tariff of 2 shillings 6 pence per cwt. Lamps, lamp ware, lanterns and lamp stoves, and all parts thereof, are taxed at 20 per cent. ad valorem. Roofing slates and unwrought slate slabs are subject to a duty of 15 per cent. ad valorem.

GOODS ADMITTED FREE.

A great many kinds of metals and metal manufactures are classed under "special exemptions" and are admitted free. These include machine tools for metal working, tinsmiths' tools, tin plates, black plates and sheets, brass and copper in bars, sheets, pipes and tubes and scrap, aluminum, bronze and nickel sheets and scrap, wrought iron and steel tubes or pipes, cream separators and testers, crucibles, &c.

The operation of the new Australian tariff will be watched with special interest, in view of the diversity of policies which were pursued in the separate colonies, and the questions which are awaiting solution as to the effect of the tariff in producing revenue, and at the same time developing the manufactures of the country. It remains to be seen whether or not the tariff will be modified in important respects, but advices received indicate that it will probably remain in force with only minor modifications.

A FEW THINGS ABOUT FURNACES.

BY A. COLLOQUY.

He was one of a corps of intelligent men who made our establishment popular in our line of trade. His work was of a clerical character, yet it brought him in contact with the practical men in all the different lines of work done by our establishment. I am one of the practical men and that is the reason that we had our little chat on the heating of his house. He had come to talk to me on a matter of business and incidentally asked if I thought that by running his kitchen range hard and having a good stove in his parlor he would be able to heat the dining room in between and make upstairs warm enough for his wife and two babies to live in. He also said that he got absolutely no satisfaction from his furnace. He had seen no end of plans of buildings and of work laid out for our men to do, and should have known how to draw a rough plan of his own house. I invited him to do this, and the caricature that he made in the attempt nearly gave me an attack of "psychical epilepsy."

In consequence of his failure to get his house warm he condemned the furnace system of heating. I was able, however, to find out that the cold air was taken from the west side of the building, and just north of it was a little extension to keep the wind off the back kitchen door and support the bathroom on the floor above, giving the bathroom the coldest exposure in the building. I explained to him that any but direct west winds would cause an eddy in this little angle and have a tendency to draw the air out of the furnace through the cold air duct, whereas a supply of air should be driven into it to be heated and sent through the pipes and registers.

Evidently he grasped the idea that in order to make heated air come out of the different pipes and registers cold air must go into the furnace at the bottom in some place. He told me that a landlord having houses in the same neighborhood had assured his tenants that a cold air box was something of a nuisance and an unnecessary expense and that all the fresh air they needed in their houses in the middle of winter could be secured by opening the cellar window for an hour in the morning. Our friend concluded that there was some sense in that, because it would not be desirable to have the cellar window open 24 hours out of the 24. I quoted to him the hymn, "I Need Thee Every Hour," and told him that if he wanted the hot air to come up in the registers every hour he would have to have cold air going into his furnace every hour. I also suggested to him that if a furnace got a continual supply of air from some place it need not necessarily be from a cold air duct leading from out of doors. I told him that the air supply was needed in accordance with a law of nature which was as old as the hills, but that many people attempted to be economical by shutting off the cold air when the weather got colder so they would not have to run their furnaces so hard.

All furnacemen can find some satisfaction in the fact that those who are foolish enough to pursue such a custom pay the penalty, for the cold air supply bears a relation that never changes to the hot air flow. If they shut off the supply of air, nature, never to be denied, will take the air supply through the cracks and crevices around the windows and doors of the most exposed and coldest room and pass it down through the register pipe that ought to be sending up warm air. The air that is thus supplied to the furnace then mingles with the hot air and is distributed through the heating pipes to rooms on the side of the building that are less exposed, and toward which the natural air pressure carries the heated currents.

I must say that my fellow worker was not in just the frame of mind to absorb the valuable information given. He had no taste for making a correct plan of his house, with the size of the hot air pipes and the dimensions of the cold air box. But when this truth was driven into him stronger he agreed to take up the task. He was of the opinion that the whole furnace system was a fake and that it would be better for him to put up some stoves, where he could see the fire and know that he was hot whether he felt so or not. Evidently his theory is that seeing is believing, and he is not aware that feeling is

the naked truth. I was able, however, in the end to get him to agree to make a plan of his house so that I could give him the causes of his troubles and the remedy for them. I told him he was living in the wrong age; evidently he belonged to the age when a man should have gone back into a cave in the winter time and had a fire built in front of it to keep the cold out.

A furnaceman who understands furnace heating may have some difficulty, just as I have had, in getting his customer to understand what he must do in order to operate his furnace so as to get satisfactory results. But once educated he is a valuable assistant in extending the demand for furnace heating. The first principle that follows the laws of nature and never can be violated without incurring the penalty is that to have hot air flow from a furnace cold air must be supplied to it with the same freedom that the warm air is expected to flow. I have said on other occasions that if either the coal or the cold air were to be omitted the furnace would give better satisfaction without the coal than it would without the cold air supply.

Now, many furnacemen absorb from their customers the idea that a furnace can have too much cold air, and in consequence they make the supply pipes smaller than they should be. After a good many years' experience I am satisfied that if the cold air supply duct has an area equal to the area of the hot air pipes, better satisfaction will be derived from the heating system than if it is smaller. In the early fall and late spring, when a fire is necessary, it is apt to make the house too hot unless there is abundance of cool air supplied to the furnace; but as the winter advances and the air is naturally colder it is a simple matter to close the damper and reduce the supply and to break the force of the wind blowing into the cold air box and yet have enough air going in all the time to fill all the hot air pipes of the furnace. It may require a little study on the part of some of the younger furnacemen to familiarize themselves with these principles so that they can explain them readily to their customers, but when they have once mastered them there is no need for anybody in their community to go back in a cave in winter and keep warm by building a fire in front of it.

The Simpson Stove and Manufacturing Company.

The Simpson Stove & Mfg. Company, whose present works are located at Liberty avenue and Twenty-sixth streets, Pittsburgh, Pa., have decided to remove their plant to Washington, Pa., where a very favorable site of land has been obtained. At a meeting of representatives of the firm and the local Board of Trade, held at Washington, on Saturday, November 9, plans and specifications for the new buildings were accepted, and a new Board of Directors for the Simpson Stove & Mfg. Company were elected, as follows: W. J. Gower, S. S. Manneil, Jr., of Canonsburgh; W. L. Clark, George A. Simpson and H. Prescott Simpson of Pittsburgh. The Simpson Stove & Mfg. Company were established in Pittsburgh about 11 years ago, and their present plant is entirely inadequate to handle their growing business. The concern do not own a foundry, but have been buying their castings in the open market. The new plant at Washington will include a modern foundry, and make the concern independent of the open market on castings. It will be modern in every respect, and will be equipped with new labor saving machinery throughout. In addition to the lines of goods now made by the concern, consisting of gas ranges and gas utensils, the manufacture of steel ranges will be undertaken. Work on the erection of the buildings will be begun at the earliest possible moment, and they will be pushed to completion as fast as possible.

THE CULTER & PROCTOR STOVE COMPANY, Peoria, Ill., have awarded a contract for the addition of another story to their plant at the corner of Water and Fayette streets. The addition has been rendered necessary by the large increase in the company's business, which has made their present facilities too small for their requirements.

HEATING GOODS IN MEXICO.

The sale of American heating and cooking apparatus in Mexico, owing to its nearness to the United States, might be looked upon by manufacturers as a reasonable expectation, and it is probable that some effort to cultivate this field may be rewarded. Before any considerable amount of business is done, however, it will be necessary to make a patient and energetic canvass for the introduction of the goods, and this must partake largely of an explanation of their merits, operation and use. The Mexicans have been satisfied with their primitive kitchen facilities, and have had but little need for heating apparatus, so that they know nothing of the convenience and comfort of the modern American kitchen range or of the oil and gas heaters and small coal and wood heating stoves that would contribute so much to their comfort when the northerly blow across the country. The need of heating apparatus is greater on the higher levels, many of the villages being located on plateaus several thousand feet above the sea level. A correspondent in Mexico makes the following comments on the attitude of the people of that country toward these conveniences:

In the mountain regions, during cold weather, it is probable that hot air furnaces might be used in some of the modern residences. There is certainly no demand for them at present, and I doubt if the people know anything about their use. The houses are quite generally of a primitive character, and even those that are pretentious are built with only one story, even to the extent of covering considerable ground, rather than to utilize a second floor, which would make it necessary to climb the stairs. The item of labor is not a matter of consideration, as it is in the United States, particularly when the Indians will carry a 200-pound sack of ore to the top of a shaft cheaper than it could be done by machinery, if the cost of the plant is reckoned.

There are plenty of modern houses on the plateaus, but, owing to their construction, they could hardly use furnaces. But among this class there should be a good demand for the cheaper and neatly finished kerosene oil heaters used in the United States. However, kerosene oil is retailing at 80 cents per gallon in Mexico City. The City of Mexico and several others are at an altitude of from 5000 to 7000 feet above the sea level, but even those who inhabit these elevated regions would require some one to educate them up to the occasional use of oil stoves when there is a norther on the coast.

Apparatus for drying fruit is unnecessary in this hot country. Evaporation is very fast on the high levels except during the winter season, which about corresponds with April in the United States. All who intend to do business in Mexico must remember that the people here who live in a really civilized fashion form but a small percentage of the total population. By far the greater part would not know what to do with an iron stove if they had one. The better classes, while more easily taught, would need some one to explain the convenience and the use of both heating and cooking apparatus if they purchased it.

Vaporizing Gas Stoves.

Some persons complain, says a British architectural journal, that gas fires cause an uncomfortable dryness of the atmosphere of a room. A series of experiments has been conducted which proves that the atmosphere of a room is not rendered more dry by the use of a gas fire provided with a flue than by the use of a coal fire, and the experimenter is of opinion that the alleged dryness is always due to a trace of the sulphur compounds in the products of combustion escaping into the room through a defective flue. Where the flue is perfect and a strong up draft is maintained no such feeling of dryness is experienced. To meet all requirements, however, most of the gas stove manufacturers now manufacture a stove fitted with a well to contain water, the water being slowly vaporized by the heat from the fire. Vaporizing fires appear to be rapidly growing in popularity, and are very serviceable for sick rooms where a moist warm atmosphere is required. A shallow pan of water

placed in front of an ordinary incandescent gas fire may, of course, be used instead of a specially constructed vaporizing gas stove but is not so convenient.

P'S AND Q'S AND A, B, C'S.

Minding their p's and q's keeps some of the old fellows in the stove business pretty busy, but they can spare time for a smile over the scheme presented by Carolyn Wells in the *Youth's Companion* to make the little fellows know their A, B, C's, particularly as the illustrations and rhymes accompanying some of the letters have been inspired by staple articles in the trade. A picture of an andiron, with the following verses, introduces the letter A:

A was an Andiron
So tidy and bright,
Who kept up the fire
By day and by night.
Amiable Andiron!

A picture of a furnace, somewhat novel in appearance, accompanied by this rhyme indelibly impresses the letter F upon the mind of the learner:

F was a Furnace
Who nearly went daft
When they asked him to draw
A check and a draft.
Funny old Furnace!

The letter R is illustrated by a range and this verse:

R was a Range
Who said, "It is strange.
My chimney flue,
Why can't I fly, too?"
Ridiculous Range!

An illustration of a stovepipe introduces the letter S with these lines:

S was a Stovepipe
Who cried out, "Oh, dear,
I've just bumped my elbow.
'Tis broken, I fear."
Sorrowful Stovepipe!

Reliable Vapor Stoves and Ranges.

We have received from the Schneider & Trenkamp Company of Cleveland, Ohio, and Chicago, Ill., a copy of the 1902 catalogue which they have issued relating to Reliable vapor stoves and ranges. It is a work of 98 pages profusely illustrated and bound in paper covers. This is the fifteenth annual vapor stove catalogue which the company have issued, and in it they state that they have grouped together a line of stoves and ranges, which have established an enviable reputation in the stove market. The policy of the company always has been to progress; to introduce new ideas and improvements possessing real merit, and by giving constant and careful attention to every detail in manufacture, they purpose maintaining the excellent qualities claimed for their productions. In the early pages of the catalogue 11 reasons are given why the Reliable single generator is the best. These are followed by illustrations showing various forms of the generator, from 1890 up to that for 1902. Important points to bear in mind when ordering repairs for a Reliable Process stove are presented, together with a price-list of repairs of various kinds. A Reliable stove is then illustrated and described in its various modifications, followed by a consideration of individual burners, torches, ovens and miscellaneous goods. A telegraphic code, which dealers will find convenient when ordering goods by wire, is a feature of the closing pages.

The company announce that in addition to their vapor stoves and ranges they make a very complete line of steel ranges, oil heaters, hotel gas ranges and gas cooking and heating appliances of all kinds.

THE KANSAS CITY FURNACE PIPE COMPANY of Kansas City, Mo., have been incorporated with a capital stock of \$5000 to make Hot Air Pipe, Elbows, &c.

BRYAN VACUUM MOLDING MACHINE.

At the eighth annual meeting of the Philadelphia Foundrymen's Association, on November 6, H. M. Baldwin of the Power Specialty Company, New York, read the following paper on the Bryan Vacuum Molding Machine:

What boy has not made a sucker out of a scrap of moistened leather and a bit of cord to lift stones and thus become familiar with the power of a vacuum in the most simple form. This principle forms the basis of the Bryan vacuum molding machine.

The first office of a molding machine is to draw the pattern from the sand more quickly, surely and accurately than if done by the most skillful molder. The natural way to do this is to lift the pattern out of the sand, leaving the sand in the flask intact. That most molding machines have been constructed so as to lower the pattern from the sand, leaving the latter suspended above, has been undoubtedly due to the failure of ingenuity to devise the method worked out by Mr. Bryan.

By lifting the pattern not only is the operator able to watch his work, but the danger of damage to the mold by dropping sand is entirely eliminated and time taken for repairs is saved. The sand in a bolt hole, for instance, would, if cracked, fall out by its own weight when the pattern is lowered away from the mold, whereas if the pattern were lifted its own weight would keep the sand in place.

The Bryan vacuum molding machine, therefore, is primarily a machine to take hold of a pattern by means of a sucker and lift it truly out of the sand. It consists of a vertical sucker rod, supported by a frame which swings on vertical hinges over a molding bench. It may be fastened to a post or column, or to the wall.

The sucker rod glides up and down in sockets, forming part of the outer extremity of a swinging frame, and is worked through a lever having a projecting handle, which is grasped by the operator when he is ready to draw his pattern.

At the lower extremity of the sucker rod is fastened the sucker head, which is formed of a soft rubber disk held in place by an annular metal plate. An opening in the center of the sucker head communicates through the sucker rod, which is hollow, and through a flexible connection, made of rubber hose, at the top with a foot power vacuum pump which is attached to the brackets supporting the machine. In case a vacuum system exists in the foundry where the machine is located the foot pump is dispensed with and the hose at the upper end of the sucker rod is connected directly to the vacuum system. Otherwise the foot vacuum pump is worked by the operator, who, with a slight effort and without moving from his position, gives one downward stroke of the pump with his foot just as he brings the sucker head into service by lowering it into contact with the pattern or board on which the pattern is mounted.

To secure a large flat surface for the sucker head to readily grasp the pattern is usually split and mounted on a board or wooden plate, which plate is provided with bushed holes or pins to fit dowel pins or holes on the flask in order to insure the proper matching of the two parts of the mold.

In operating this machine the pattern board is first laid flat on the molding table with the pattern up. A flask is then laid over this, allowing the dowel pins to enter the holes in the board. The flask is then filled with sand in the usual manner and rammed by hand or with a squeezer, the top flushed off and a bottom board laid on. The flask and two boards are then turned over by hand and allowed to rest on the molding table, with the pattern board on top. The pattern is then jarred to loosen it by striking the board to which it is attached with a mallet, and the operator grasps the handle on the lever and draws down the sucker rod until the sucker head comes in contact with the pattern board. In descending a valve or cock on the sucker rod strikes a tappet and opens communication between the sucker head and the vacuum pump. The sucker grasps the board carrying the pattern and the operator throws the lever up, and thus, assisted by an affixed counterweight, the sucker head draws the pattern quickly and truly into midair. At the proper distance from the mold the cock on the sucker rod is again thrown by a tappet, thereby disconnecting the sucker head from the vacuum and opening communication between the sucker head and the atmosphere, thus releasing the pattern and board, which fall readily into the hands of the operator, who has in the meantime let go of the handle by which he raised the sucker rod.

A small dash pot attached to the frame and the lever keeps the sucker rod from flying up too quickly. The flask containing this portion of the mold is then placed

on the floor and is ready to receive the other part, which is prepared in a like manner.

More than one operator can use the same machine, as the length of time required for drawing the pattern is considerably less than that required for filling the flask. The machine is easily swung to and fro, so as to be used by each man as he is ready to draw.

A pneumatic rapper is often attached to the sucker head, receiving its supply of air through a small flexible connection, and fitted with a cock, also controlled by tappets, so as to put the rapper in operation automatically only while the pattern is being extracted from the sand.

It will be seen that the machine is extremely simple in construction and operation. A few hours' practice will enable a green hand to make a perfect mold, and rapidity of operation follows very soon.

The preparation of the pattern for the machine requires very little expense, as almost any form of wooden pattern may be used by merely mounting it on the match board. Once attached to boards in the pattern shop the change may be made on the machine from one pattern to another as often as desired and without loss of time, which advantage is very great when but a few castings are required from any one pattern. As many flasks can be made from any number of patterns in the same time that the same number of flasks can be made from one pattern.

The saving in the doing away with the stripping plates also gives the machine a decided advantage over other forms, and opens up opportunities for machine molding which would otherwise be lost.

The use is not confined to any particular size of flask, but may be described as general for any style of bench work.

By mounting the two parts of a split pattern side by side on the same board two castings from but one pattern may be made with one operation, as the impression made by one half in the cope covers over the impression made by the other half in the drag, while, to carry this same idea still further, one half of a symmetrical pattern may be used with equal facility to form a complete mold.

In addition to green sand molding this machine finds a useful field in core work by using it to lift the boxes from complicated cores.

The machines are made in two styles, one of which may be set up in any foundry by attaching it to a post or column, or even a wall; the other is self contained. They are furnished with or without the foot vacuum pump or pneumatic rapper, and all the special features are fully covered by letters patent.

Although they have been on the market but a short time, the interest which they have already created, as proved by the activity for trial orders, encourages the builders to believe that they are destined to satisfy a long felt want.

ODD PLATES.

At the annual meeting of the stockholders of the Monarch Stove & Mfg. Company, Mansfield, Ohio, recently held, the following Board of Directors was elected for the ensuing year: A. B. Martin, Emmett C. Baxter, R. B. Maxwell, B. A. Baxter, Edwin D. Baxter, L. J. Bonar, J. C. Liser. The board organized by the election of A. B. Martin, president; R. B. Maxwell, vice-president; Emmett C. Baxter, secretary and general manager, and B. A. Baxter, superintendent. A dividend of 4 per cent. on the stock of the company for the eight months on the present year's business was declared, and the balance of the profits was ordered carried to the surplus account.

A LARGE addition is being made to the Excelsior Stove Works, at Quincy, Ill., at a cost of about \$40,000. The new building will adjoin the present main building of the company, and will be of the same width and 270 feet long.

THE South Indianapolis Improvement Association of Indianapolis, Ind., announce that they have secured an Eastern Stove and Range foundry for the new industrial suburb of South Indianapolis. The concern, it is stated, have a capital of \$500,000 and employ 400 men.

THE SCHILLINGER STOVE COMPANY, Syracuse, N. Y., have brought an action against the city of Syracuse to recover \$500 for damages done to the company's stock by reason of the overflowing of a street sewer. It is alleged that the sewer was improperly constructed, and that the city officials had full knowledge of the fact.

THE H. ADLER COMPANY, Pittsburgh, Pa., are attracting the attention of buyers of gas goods to their line of Acme Gas Stoves and Grates, by the distribution of a card printed in colors, showing two children standing in front of a gas grate enjoying the warm glow.

THE ENTERPRISE STOVE COMPANY, Vincennes, Ind., call attention in a four-page folder to the merits of the Domestic Star Steel Range and the Star Radiator Parlor Heater. The former is made in a variety of styles and sizes and embodies the latest improvements. The Heating Stove is made in two grades and is constructed on entirely different principles from those involved in "air tight Heaters." By removing the urn and attaching a hot air pipe a Double Heater is provided.

A LEAFLET, which is being sent out by Gorman & Millett of 46-48 West Market street, Wilkes-Barre, Pa., calls attention to the Wrought Steel Ranges which they manufacture in all sizes. The point is made that these Ranges are "built like a battle ship, for durability and service, and to stand hard knocks." The goods are turned out in sufficient variety to meet every requirement. In addition to Ranges the manufacturers turn out Steam Tables, Warming Closets, Plate Warmers, Hot Closets and Mammoth Coffee and Tea Urns. Contracts are taken for the equipment of kitchen cooking apparatus for hotels, restaurants, steamships, private families, &c.

THE COLE MFG. COMPANY of 3218 to 3238 Western avenue, Chicago, Ill., are erecting a fire proof warehouse at their plant, which is estimated to cost about \$30,000. The structure will cover an area 150 x 50 feet in size and will be three stories in height. The company expect to add a great deal in the way of equipment in order to meet the growing demands of their business. They have a surprise in store for the trade in the way of a new Range, which they expect to bring out next season.

THE GALUSHA STOVE COMPANY, Rochester, N. Y., are sending to their friends in the trade a folder calling attention to the Norman Stoves and Ranges, which they manufacture in great variety. The company point out to dealers that if they do not order very soon they will be too late to get in line with other up to date merchants, "who are now reaping a golden harvest by handling the Norman Stoves." The company intimate that if the dealers are as wise as they think they are they will put in an order for at least a trial shipment, or send for the company's finely illustrated catalogue.

In an article appearing in our issue of October 26, giving a review of the Stove dealers' supply catalogue of Kramer Brothers, proprietors of the Dayton Stove Repair Works of Dayton, Ohio, the statement was inadvertently made that the concern are manufacturers of the Diamond Extension Stove Backs. We are advised by the Adams Company of Dubuque, Iowa, that they are the sole manufacturers in the United States of these Stove Backs. The Kramer Brothers are jobbers of these goods.

THE IDEAL FOUNDRY COMPANY of Girard, Ohio, is the name of a new company with a capital of \$35,000, formed by the consolidation of the International Range & Mfg. Company and the Ideal Foundry Company of Girard.

GEORGE W. McFADDEN, 186 Minot avenue, Auburn, Maine, who bought at auction the plant and stock of the Auburn Stove Foundry Company, is making repairs of all kinds for the Auburn Stoves, and is prepared to furnish them to those in need of such repairs.

In their advertisement, on another page the Ringen Stove Company of St. Louis, Mo., call attention to their well-known line of Quick Meal Gasoline and Oil Stoves for the season of 1902. The makers claim the Quick Meal will be better than ever, many new improvements having been introduced. The high standard of material and construction which has always characterized this line will be strictly maintained. It is interesting to note the statement that the sale of Quick Meal Steel Ranges has doubled during the past season. Dealers are urged to apply early for exclusive agencies.

THE READING STOVE WORKS, Orr, Painter & Co.,

Reading, Pa., have favored us with one of their handsome leatherette standing desk calendars, which they are distributing to the trade. These calendars are arranged to be used for the years 1901 to 1907, and are tastefully ornamented in gilt, with the name of the firm, their various branch offices, &c., in gilt letters. The days of the week, the months and years are turned by means of brass thumb screws, and the name of each day is surmounted with photographic reductions of some of the various lines of Stoves, Heaters and Ranges manufactured by the concern. Monday illustrates the Mystic Sunshine Range, Tuesday the Othello Range, Wednesday the Colonial Sunshine Range, Thursday the Sunshine Oak, Friday the Golden Sunshine Heater, and Saturday the Tropic Sunshine Furnace.

THE ILLINOIS STOVE COMPANY of St. Joseph, Mich., have been incorporated with a capital stock of \$5000 under Illinois laws.

AMERICAN STOVE BOARD COMPANY, Chicago, have prepared plans and specifications for a large factory building to be erected on property adjoining the present site of the company's works. The new building will be nearly double the size of any of the present structures, and will enable the company to greatly facilitate their work, as well as to give employment to several hundred additional workmen.

WE are informed that the S. Obermayer Company, Cincinnati, Ohio, have opened a warehouse in Pittsburgh, corner of Thirty-fifth and Charlotte streets. The company will carry a full line of Foundry Facings, Supplies and Equipments there, and will be in a position to fill all orders promptly. This branch will be known as the Pittsburgh branch of this company.

THE CHARTER OAK STOVE & RANGE COMPANY, St. Louis, Mo., say the difficulties which they have experienced on account of the delay in obtaining and scarcity of material have now been overcome. They report the demand for their products unusually heavy, and although they have increased their facilities, enabling them to turn out more than 600 Stoves per week more than in corresponding period of last year, they are still hard pressed to promptly meet all requirements.

W. H. COLEBROOK, SONS & Co., Syracuse, N. Y., are attracting attention to their Black Flag Stove Polish Benzine Paste for the use of Stove dealers by the distribution of a circular presenting the portrait of an honest man, who stands for this Polish and Colebrook's Asbestos Furnace Cement and Stove Putty, on the ground that they are the best and that there is nothing "just as good."

A LITTLE FOLDER which is being distributed by the Michigan Stove Company sets forth the merits of the Front Glow Oak Garland Parlor Heater, designed for using soft or hard coal, coke or wood as a fuel. The construction is referred to as being original and as giving two large front and full base heating flues to an Oak Stove. The fire pot is heavy and can be furnished either single or double, as required. The body of the stove is of cold rolled boiler iron. The front door has mica illumination, and the Stove is fitted with heavy shaking coal grate, or patent cut off grate for wood.

WE are advised by the Peerless Steel Range Works of Chicago, Ill., that the statement published in our issue of last week to the effect that they have decided to move their plant to South Milwaukee, Wis., is incorrect. Although they received a very flattering proposition to locate in South Milwaukee, no negotiations are at present in progress, and the company intimate that they are not likely to make a change at any time in the near future.

THE BRONSON-WALTON COMPANY, Cleveland, Ohio, makers of Coffee Mills, Roasting Pans and Hardware Specialties, have moved into their new plant, which has been building during the summer. They have added new machinery which will double their capacity. They report plenty of orders and are running a night force. One hundred men are employed.

PERSONALITY AND HUMAN NATURE AS ELEMENTS OF COMMERCIAL SUCCESS.

BY F. E. BONNEY.

"There is a great deal of human nature in man," says Judge Haliburton, and he followed the statement with the further one that, "there's more in woman." "Nature draws more than ten oxen," says another of the old philosophers. Horace says, "Though you cast Nature out with a pitchfork, it will still return." "What's born of a hen will scrape." The Spaniards have a proverb that, "The son of an ass brays twice a day."

BUSINESS FAILURES OR SUCCESSES.

In seeking for the causes of business failures or successes it has often appeared to me that both writers and speakers have frequently failed to take cognizance of elements which contribute not a little to success or failure, or, if they have recognized such elements, have failed to give them the importance which they really deserve.

This may be because such elements do not appear prominently upon the surface, but rather beneath it, or, when they do rise above, are not always recognized by their proper titles. I refer to personality and pure human nature.

These elements have guided or misguided the affairs of men from the time when Eve's overweening curiosity made her a prey to the serpent and Adam fell a victim to feminine cajolery, to the present twentieth century, where human nature is the same, though clothed in the garb of more modern times. The cat, though transformed to a bride, will still pounce upon the mouse, as in the days of Æsop.

TENDENCIES AND PECULIARITIES.

We come into the world human and endowed with a nature that has accompanied the race through all the ages. We each and all of us may have our especial and particular mental peculiarities or tendencies, but others have had them before us and others will have them after us. They are mostly natural and subject to well known and fixed laws.

In general we are much alike and many tendencies we all have in common. Still each individual has a few little peculiarities very much his own, and these we soon come, to some extent, to recognize in each other. We may not all agree as to the importance these tendencies and the knowledge of them in each other play in the game of business, but all will, I believe, agree that they cut somewhat of a figure.

IT IS HUMAN NATURE

to locate the causes of success largely within ourselves and to place the blame of failure upon outside causes and influences. One man succeeds because he has a disposition and mental make up which makes him friends and draws him trade from all directions. Another who lacks the personality of the first succeeds because he understands human nature in others and knows how to play upon and guide into proper channels their various peculiarities and inclinations.

One man fails because his personality is bad, though his methods may be good. Another fails, though his personality is good, because he does not understand and appreciate the many peculiarities and tendencies of his fellows. Many succeed and many fail without ever fully realizing or appreciating the real forces which lie at the bottom of their success or failure. The man who is thoroughly conversant with Nature's laws and who knows the causes of certain effects and how to produce, regulate or take advantage of them, has a strong lever with which to do his work.

SELF PRESERVATION

is the first law of nature. It is born with us. It is intuitive. It doesn't wait for reason, judgment or fairness. This is shown in times of great danger by the selfishness and brutality of many from whom we would least expect such an exhibition.

We may say we would not exhibit such a spirit. Wait till we are tried. Next to me is mine. Next to us is ours. This is natural. Now for the application. A man starts in business with ample capital, a good location and all

the outward needs for a successful career. He has a bad personality. Customers do not like him. They may think he means well, but they don't like to trade with him. He fails. Why? Will he be honest as to the cause of his failure, even should he know it? If the department store man across the street was a pleasant fellow, will he not lay it to him and his competition?

Another starts out likewise well equipped as to capital, location, &c. He has a pleasant and attractive personality. He is a good fellow. He cannot say "No" to the salesman who asks him to take a gross, instead of a dozen. He can't say the little word to the other good fellow, who wants the goods to-day and will pay next month, next fall and perhaps finally in pork. He fails. Why? Will he be honest? If the catalogue house man in the city bought carefully and sold for cash, will he not lay his failure to catalogue house competition?

SELFISHNESS.

There is nothing more human or more natural than selfishness. This is seen nowhere more forcibly than in trade. Your customer as a rule does not go to the department store or send to the catalogue house because he dislikes you, but because he believes he can do better for himself and his. If the catalogue house or department store man gets his trade, it is because they have made him believe this. They recognize this trait of human character and cater to it. Wouldn't you do the same if you had the capital and the opportunity? Now be honest.

Do you try to take advantage of this human selfishness, and try to show your customer how he is doing best for himself and his by trading with you, even if he has to pay a slightly higher price? Do you show him how some of the money he pays you stays at home to keep up the local church, school, fire company, &c., and do it pleasantly, effectively and persistently? Or do you jump upon him and the catalogue house rough shod and often miss the truth and too sharply attack the customer's judgment, which is a very tender point with him?

How many customers, if too roughly convinced of an error, will refuse to correct the same, simply as a matter of personal pride, or through a dislike to openly come out and admit their judgment was wrong.

PROSPERITY DESPITE COMPETITION.

There are hundreds of merchants to-day in cities and villages who are successful and prosperous, notwithstanding much severe competition. They are selling large quantities of goods, getting fair prices and making nice profits and accumulating a competence. In these same cities and villages are other merchants who are not thriving, though they have practically the same conditions to meet.

I do not wish to appear to argue that personality is everything or that an acute knowledge of human nature will always accomplish desirable results. I do, however, believe that these elements are important factors in business success. Barnum said that people liked to be humbugged. They evidently liked Mr. Barnum's way of humbugging. He was careful, however, that his humbugs had no stings. How many men have made fortunes from a knowledge of pure human curiosity? How many men have traded to their profit on human credulity and hope?

A knowledge that men can be easily made to believe what they really want to believe has enabled many a man to enlarge his bank account. In our fights against many evils we have, I fear, many times lost sight of some of our most effective weapons.

We sometimes abuse the catalogue house and department store man. He is doing simply what you or I would do were we in his place, provided, of course, that he is at least fairly honest, and most of them doubtless are. He is buying where he can do the best, selling for cash and making some money. He understands human nature. This knowledge is a part of his stock in trade and it is yielding him good returns. As long as he is honest we should not criticise him. If he is dishonest and unfair he should be punished, and in any case his sins will ultimately find him out.

The man who sells the department store and the cat-

atalogue house at cut prices and allows them to cut prices to the consuming public to a point where the honest retailer cannot compete is the man we are after. His own selfishness has blinded his vision and overshadowed his judgment of the rights and nature of others.

THE MANUFACTURER AND THE JOBBER

are the men we must educate, but we must not attempt it with a club. The tendency of several generations cannot be dissipated in a year. These men know something of the laws of equilibrium and can be taught that the selfishness of a few hundred men cannot stand against the selfishness of several thousand. They are interested in themselves and theirs and will follow the paths which lead to the best results. A few might be driven into these paths. All can be led. There is also a widespread love of absolute and exact justice among men, and the majority will always recognize this principle. Those who will not quickly recognize self interest.

GIVE THE RETAILER AN EQUAL CHANCE.

Justice demands that thousands of retailers scattered throughout the land in close touch with the consuming public shall have an equal chance with the department store and catalogue house to make an honest living. There should be equality before commercial as well as before constitutional law. If an appeal to justice fails then let there come an appeal to selfishness. The manufacturer and the jobber are in the market to sell goods at a profit. Who buys the most and pays the best prices, the thousands of retailers, or the hundreds of department stores and catalogue houses?

A CONTINUED AND PERSISTENT APPEAL

to justice and selfishness will settle these questions.

In pursuing these methods nature and personality should not be lost sight of. Study your men. Use tact and ever keep in mind the influences which govern and shape human conduct. Be fair, be calm, be persistent and, above all, be just.

We all have our troubles. We always have had them. We always shall have them. The mills of God grind slowly, but the product that comes from the outlet is always the pure and refined grain, free from chaff and cheat.

Study your mental philosophy, master your moral philosophy and apply the knowledge gained from both to your every day business and social relations, and if you don't achieve at least fair success then the lessons which are intended to be conveyed in this article are all wrong.

Stove and Hardware Dealers.

THE CLARK HARDWARE COMPANY, Black Hawk, Col., have been incorporated with a capital stock of \$25,000 to carry on the wholesale and retail business in Shelf and Heavy Hardware, Stoves and Tinware, Agricultural Implements and Mine and Mill Supplies.

ALUMINUM MFG. COMPANY, Two Rivers, Wis., are distributing a circular illustrating their line of Aluminum Goods, including Oil Cans, House Numbers, Key Chains, Match Safes and Holders, &c. They have recently commenced the manufacture of Aluminum Playing Cards.

THE AVERY STAMPING COMPANY, Cleveland, Ohio, have added a smaller sized Steel Spider to their line of Never-Break Cooking Utensils. It is designated as their No. 6 Breakfast Spider. The cooking surface of this size is 7 inches in diameter. It is referred to as very handy for cooking small quantities of ham and eggs, &c. The company state that they have encountered a demand for a Spider of this size, which is especially adapted for use in families where there is only a small meal to be cooked, and they are expecting to have a large sale of it.

THE CARNAHAN ENAMELING & STAMPING COMPANY of Canton, Ohio, have broken ground for their new factory in that city. The company's plant will be on a large scale, and they will draw their raw material from local works.

D. R. BALL & SON have embarked in the Hardware, Stove and Tinware business at Juniata, Neb.

Graphite.*

The use of graphite in the world's industries is rapidly increasing, not only in the amount and value of material, but also in the number and variety of its applications. Beginning in the middle of the sixteenth century with its use in the manufacture of lead pencils, followed perhaps a century or more later by being used in the manufacture of melting pots, its sphere of usefulness has so broadened that to-day it occupies a distinct and very important place in the world's industrial scheme.

Before describing its various uses, it may be of interest to present somewhat briefly something concerning its names, natural formation, general occurrence, sources and amount of supply. The words "graphite," "plumbago" and "blacklead" are practically synonymous terms, in that they refer to the same chemical substance. The term "blacklead" was probably the original, and a comparative one, comparative because it indicated the color of the streak made by this substance as compared with that made by metallic lead, evidently in very early use for the purpose of writing or lining on paper. From the word "blacklead" the word "plumbago" naturally developed through the Latin. The word "graphite" is from the Greek; meaning in the original, "I write." Thus it will be seen that all these names have reference to its very earliest use—that of making pencils. While these three forms are synonymous, there have come to be certain peculiar applications in their uses—thus, we import plumbago from the island of Ceylon, and blacklead from Germany, Austria and Italy, and, at the same time, we export graphite from this country to all the other countries of the world. There are lead pencils, plumbago crucibles and graphite lubricants, blacklead stove polish, plumbago foundry facings and graphite paint. This confusion of names may seem to be somewhat misleading at times, but there is considerable method in it.

WHAT GRAPHITE IS.

Graphite may be regarded as occupying the middle place in the carbon triad—charcoal and the diamond being the other forms—but has its own individual characteristics, which make the number of its useful applications much greater than that of either of the others.

Graphite occurs naturally in two forms—the amorphous and the crystalline. The amorphous graphite does not occur pure, but is always associated with some other earthy materials, the character of which have great bearing on its use. Crystalline graphite also shows great variations, because of the distortion of its crystals during the process of formation. It occurs both massive and with its particles disseminated through a containing rock; thus Ceylon graphite occurs in large masses of crystals, while the American formation is usually found as a small laminated flake disseminated through granitic rocks.

WHERE FOUND.

At the present time the world's annual production of graphite probably approximates 60,000 tons, and of this amount probably 50 per cent. is of the crystalline variety and the balance of the amorphous form. Of the crystalline graphite, at least 90 per cent. comes from the island of Ceylon, and of the amorphous form, probably the same relative proportion comes from the interior States of Germany and Austria. The remainder is nearly all supplied from the mines of Canada, New York and Mexico.

The first importation of Ceylon graphite into this country was made in 1829, by Joseph Dixon of Salem, Mass. Two years previous to this he had experimented with graphite from the State of New Hampshire, as a substitute for German blacklead, or pot lead, as it was sometimes called, in the manufacture of crucibles. The success of his experiment in this line was so pronounced that he secured a small shipment of Ceylon plumbago, samples of which he had previously seen in the possession of sailors in the New England ports. This was the first use of crystalline graphite in the manufacture of

* Abstract of an article by Malcolm McNaughton in the *Stevens Indicator*.

crucibles, which particular branch of the graphite industry now absorbs probably somewhat more than one-half of the world's output.

ITS USES.

The total output of graphite is consumed in something like the proportions indicated in the following table:

Crucibles	55
Stove polish.....	15
Foundry facings.....	10
Paint	5
Lubricating	5
All others.....	10

The various uses to which graphite is put depend on certain physical characteristics which it possesses, none of its uses, except as a foundry facing, involving any chemical reaction. These physical properties are its infusibility at temperatures below that of the electric arc, its great capacity for absorbing and transferring heat, the comparative high electrical conductivity and its unctuous softness. The latter expression sounds rather peculiar, but is meant to describe that quality of yielding by contact with other surfaces, and which is the reason for its use in lead pencils, lubrication, powder glazing, stove polishes, &c. It adheres readily to any surface with which it comes in contact, and is highly polished by the slightest friction.

LEAD PENCILS.

The use of graphite in the manufacture of lead pencils is the oldest, and is now its most common one.

The lead used in the manufacture of lead pencils is of the amorphous form, and is supplied principally from the mines of Austria and Mexico; the latter product having only recently come into the market for this purpose, but seems to be rapidly taking the place of that from other sources. The pencil making industry, although not using very great quantities of blacklead, is a very considerable one; probably 15,000 people being employed in the industry in this country, Germany and Austria.

FOUNDRY FACINGS.

The practice of facing molds in which castings are to be made with some carbonaceous material is general. The material used is usually anthracite, charcoal, or graphite. The reason for its use is for the purpose of preventing the adhesion of the iron to the sand of which the mold is made. The principle of its use for this purpose is as follows: The air contained in the mold, and which is carried in by the stream of molten metal, furnishes oxygen for the combustion of the carbon material of which the facing is composed, so that a condition obtains analogous to that of the spheroidal condition of a drop of water on a hot surface; thus the iron is effectually prevented from coming in actual contact with the sand, so that when the casting is removed it will be found to be covered with a thin crust which will easily peel off, leaving the iron smooth and clean. In order to secure perfect results certain conditions must prevail.

1. The facing must adhere perfectly to the mold surfaces. The hot metal coming in contact with the sand dries it out, and if the facing has not been properly compounded it will be washed away in front of the advancing metal, so it is necessary to have a certain percentage of clayey material mixed with the facing to prevent its running before the metal.

2. It must be slowly combustible. If the facing burns quickly trouble is likely to ensue from two causes:

- a. Too great volume of gas to be readily vented, this causing "blows" and "cold shuts;" the latter term being applied to those cases where the iron has not filled the mold.

- b. Where combustion is too rapid it is not likely to endure during the entire time that the metal is in the fluid condition, so that while at first the spheroidal condition exists it ceases before the metal has solidified—thus giving every opportunity for adhesion.

Castings which have been made in connection with the use of a facing well suited to the particular case are superior because of a finer surface texture, of ease of cleaning and less tendency to dull the cutting edges of

machine tools. Plumbago is the one material which combines in a greater degree than any of the others the requisites that are necessary to a good facing. It contains no volatile matter, and it burns evenly and slowly, so that a less quantity may be used. It has, in addition, another quality, that of ability to being sleeked or polished, giving the smoothest possible surface to the mold.

AS A LUBRICANT.

One of the most interesting features of graphite is its use as a lubricant. This use is a comparatively new one. The crystalline graphite is the only form suitable for lubricating purposes, because the amorphous form is always associated with impurities. While any pure, soft, crystalline graphite is valuable for lubricating purposes the laminated form is especially adapted to this use.

Another and exceedingly important use to which graphite is applied is in the process of electrotyping, where it is used on the face of the wax case to prevent adhesion of the type form. It also supplies a conductive coating the surface of the mold. Considerable quantities of crystalline graphite are also used for the purpose of glazing gunpowder, in order to prevent absorption of moisture and consequent caking.

STOVE POLISH.

Stove polish is one of the common articles in which graphite is used in large quantities. All varieties are used for this purpose, the amorphous blacklead from Germany in the largest quantities. The polish consists of two components, the graphite which imparts the polish and the clay binding material which holds it in place. The German blacklead can be used without any admixture, but the addition of crystalline graphite gives a more brilliant but grayer luster, far more enduring and obtained with much less labor.

GRAPHITE PAINT.

During the past decade the use of carbon as a paint pigment has steadily increased, and the form of carbon now most usually employed for this purpose is graphite. Every one is familiar with the great durability of paint made from lampblack and linseed oil, and also with the very great disadvantage in its use, that of extremely slow drying. Paints made with graphite as a pigment seem to have all the durability of the lampblack paint, with the advantage of drying in a reasonable time without the addition of dryers. As a paint pigment graphite is absolutely inert, producing no injurious effect whatever on the oil, and not subject to any change as the result of any exterior conditions. One of the peculiarities of graphite paint is the extreme ease with which it may be worked out under the brush. This is due to the same quality which makes it a good lubricant. The workman finds himself spreading it out properly in spite of himself—it being actually easier to spread it out than to apply heavy coats.

OTHER USES.

Crystalline graphite is used for polishing the bottoms of racing craft, and has been brought into requisition in preparing large steamers for their speed trials. It is also used in the form of wire, rods, plates and pieces of various shape for electrical purposes on account of having very great range of electrical resistance.

The last use of graphite to be mentioned is that of a substitute for red lead for use on threaded joints, gas-kets, &c. Its advantages for this particular purpose are that the mixture never sets hard as red lead does, and joints may be readily opened, even years after they have been put together. And also, owing to the lubricating quality of the graphite, pipes may be screwed up at least a half a turn more on the average.

In a letter to *The Iron Age* John M. Hartman of Philadelphia says that the oldest casting machine known to him is at the lead works of John T. Lewis & Son in that city. It has an endless hinged table of molds, each mold lipping over the next one, and has a hammer on each side of the machine to knock the casting out of the mold. This machine has been in use for fully 50 years.

The Cleveland and Chicago Resolutions.

Special Meeting of the National Committee Confederated Supply Associations.

Owing to the somewhat radical steps taken by the Executive Committee of the National Association of Master Plumbers at their meeting at Cleveland, Ohio, in abrogating the arbitration and conciliation features of the New York Conference Resolutions and adopting the Cleveland Resolutions, printed a short time since in *The Metal Worker*, without any provision for arbitration, a method of settling differences that is growing in popularity, the whole plumbing trade will be interested in the attitude of the National Committee of the Confederated Supply Associations, as manifested in their action this week at Chicago.

The meeting of the National Committee of the Confederated Supply Association held in the Auditorium Hotel, Chicago, on November 12 and 13, was a special one, and of recognized importance. A full representation of the committee was present either in person or by proxy. This meeting was called for the purpose of considering the Cleveland Resolutions adopted by the Executive Committee of the National Association of Master Plumbers at a meeting held in Cleveland, Ohio, on October 8, 1901. These resolutions the National Committee of the Confederated Supply Associations do not recognize, and under date of November 12 the following resolutions, known as the Chicago Trade Resolutions, were adopted:

"Whereas, The National Committee of the Confederated Supply Associations has received official reaffirmation from the Executive Committee of the National Association of Master Plumbers that they insist upon the abrogation of the New York Conference Resolutions. Therefore, be it

"Resolved, That still believing in the spirit of conciliation and arbitration, we adopt the following trade resolutions:

CHICAGO TRADE RESOLUTIONS.

"Section 1. Manufacturers and jobbers shall hereafter sell plumbing goods to such jobbers as are officially recognized and to all legitimate master plumbers as hereinafter defined, and to such other parties as are included in list of exceptions hereinafter enumerated.

"Sec. 2. Definition of a legitimate master plumber.

"A party who represents the industry of plumbing, who has an established place of business, doing a general merchant and contracting plumbing business with the public generally, who has qualified under the State and local enactments regulating plumbing and plumbers, where such exist; or, where no license is required, who fulfills the other requirements and represents the industry of plumbing in the locality.

"Sec. 3. The following are entitled to buy plumbing goods: Federal Government, State and county institutions. Also water works, railroads, steamship companies, shipbuilding companies, car building companies, packing and stock yard companies, educational and charitable institutions, municipalities, manufacturing companies, for use only in the requirements of their business, providing they are regularly employing journey-men plumbers the year round to install same.

"No plumbing material shall be sold to any of the aforementioned parties for the use of any officers or private individuals connected with said excepted parties.

"Sec. 4. Plumbing goods may be sold to all manufacturers who use such goods as a part of their finished product, and when so sold by them.

"Sec. 5. No plumbing material shall be sold to department stores, mail order or catalogue houses, buildings, office buildings, hotels or retailers not doing a legitimate plumbing business

"Sec. 6. No material shall be furnished to any building that is in default to any plumber or supply house.

"Sec. 7. The National Committee of the Confederated Supply Associations is the recognized representative body or authority for and in behalf of the affiliated supply and manufacturers' associations, and to such committee all trade questions shall be referred; and it shall be the duty of said committee to hear and adjust the same promptly and to confer and advise with the Executive Committee of the National Association of Master Plumbers, and to use all proper means to preserve harmonious relations with them."

The following letter was also addressed to E. D. Hornbrook, president of the National Association of Master Plumbers, by C. W. Woodward, secretary of the National Committee of the Confederated Supply Associations:

"Replying to your letter of October 14, it is with deep regret that we learn of the fixed determination of the committee of the National Association of Master Plumbers to abrogate the New York Conference Resolutions, for we believe that these resolutions represented the careful thought and best sense of both parties thereto, and in most particulars were satisfactory as a working proposition.

"We further desire to place upon record our firm conviction that the action of the said committee has been hasty and unwise.

"We also desire to repudiate all statements and insinuations intended to convey the impression that the cause of the severance of the agreement heretofore existing has been the fault of the manufacturers and dealers, but call attention to the fact that the responsibility for the failure to enforce the New York Conference Resolutions in the Clow case rests as fully upon the Executive Committee of the Master Plumbers' Association as upon us.

"We desire further to say that we are firm believers in trade protection, arbitration of all trade difficulties, and in co-operation between the dealers and the plumbers, and hold ourselves ready at any time to confer in regard to these subjects."

The P. and S. S. League.

The team of F. Adey & Co. appeared at the alleys in the Plumbing and Steam Supply League bowling tournament in New York on Monday night with but three men, owing to sickness of the other two members of their team, and in consequence lost two games, leaving the contest between the teams of the John Simmons Company and the Dimock & Fink Company. The former won two games during the evening and the latter broke even, the feature of the evening being W. A. Presby's score of 196.

On Thursday night the team of the Ronalds-Johnson Company, New York, were made happy by winning two games. The C. S. Locke & Smith team won and lost, while the Thomas G. Knight team lost both games, one with a score of 671 against 673, the score of the Ronalds-Johnson Company team. C. A. Blanchard of the C. S. Locke & Smith team made 183 and repeated in 193. W. S. Gibbs made 189, and enabled the Ronalds-Johnson Company team to win their second victory. The contests are spirited, and the interest of the trade in them seems to be only awakening.

The call has been issued for the semiannual meeting of the Master Steam and Hot Water Fitters' Association of the State of New York, to be held in Syracuse on Tuesday, December 10. The meeting will be called to order at the Yates Hotel, at two o'clock in the afternoon, and the Executive Committee will hold a session at ten o'clock in the morning of the same day at the hotel, for the purpose of considering matters which have been brought before it, and anything that may be presented by the members which may require attention before the convention opens. The call not only invites the attendance of members of the association, but of all who are engaged in the heating contracting business.

Piping for Hot Water Heating.

BY A. B. C.

Those who are called upon to take up hot water heating as a branch of their business are often mystified over the one-pipe, two-pipe circuit and overhead systems; but when they are once explained and fully understood, either of these systems can be promptly selected

Piping for Hot Water Heating.—Fig. 1.—The Overhead System.

as best adapted to the conditions to be met in a building. Under proper conditions either the one or two pipe system of hot water heating will work satisfactorily. It is more a question of determining which of the systems is the best adapted for the building to be heated than upon the merits of any particular system in general.

In a building which will permit it, I would prefer the overhead system, shown in Fig. 1, where the main flow pipe is carried to the attic, and the main there carried

Fig. 2.—Modified Two-Pipe System.

along, pitching down and reducing in size as each branch is taken off it. The drop mains are of one size to the cellar, where they join into the return main to the boiler. The expansion tank is connected to the highest point of the main flow pipe and through this tank all the air in the system is expelled. The radiators are connected with one valve top and bottom to the drop mains.

In another case, where the building is small and the heater centrally located, I would run each flow riser separately from the boiler and carry a corresponding return main back, as shown in Fig. 2.

The usual two-pipe system is shown in Fig. 3. In this system the flow main and risers reduce in size as connections are taken off from them, while the return pipes correspondingly increase in size. Where large radiator connections are taken off a riser it is well to take them out of the straight run of the pipe and to continue the riser from the side.

In the case of a large hall or church, where the radiators are located mostly around the side of the building and the cost of the main is of considerable importance, the single main or circuit system shown in Fig. 4 is very suitable. The main is carried up near the cellar ceiling and thence around the cellar, pitching down, and finally back to the boiler. The flow connections for radiators

Fig. 3.—Two-Pipe System.

are taken from the top side of the main, while the returns are brought back into it on the side. Special fittings made for this purpose may be used.

In installing a hot water heating apparatus the pipes should always be properly graded so that there will be no traps or pockets for air to lodge in. The returns should never flow or butt against each other, and all pipes should be so proportioned that, as far as possible, the velocity of the flow may be the same in all parts of the apparatus.

The expansion tank may be connected to any of the risers, or, better still, a separate line may be run from

Fig. 4.—Single Main, or Circuit System.

the boiler without a valve on it. Or, if the tank is located in a cold place, both flow and return connections may be made to it. If there is a supply tank in the building or city water supply, use an expansion tank with ball cock. If there is a valve anywhere between the boiler and expansion tank, a safety valve should be used. I would also recommend an altitude gauge, or at least a try cock on the boiler, so that a person may satisfy himself that there is water in the apparatus before starting the fire. There should also be some kind of an automatic damper regulator for preventing damage from overheating; the most dangerous feature of hot water heating. I do not approve a closed expansion

tank. All indirect radiators should have valves which do not shut off the circulation entirely; otherwise, if neglected, these radiators are liable to freeze up.

There are well established rules and tables regarding sizes of pipes and radiators to be used, which any of the manufacturers of these lines of goods will be glad to furnish, and which it would be good practice to follow. Still, in determining the size of the radiators it would be well to remember that while the amount of heat given off by a certain radiator is easily determined, it is entirely different in determining the heat required to warm a certain room. While a great deal of expert figuring has been done in this line and tables compiled from tests have been published, which are useful guides, still the fact remains that after all has been considered it is in a great many cases a matter of good judgment in applying them to practice. I am inclined to believe that a person who blindly follows some stated rule, both as regards method of piping and sizes of radiators, will more often fail than he who uses good judgment and more liberal methods.

It is much better to use radiators too large than too small in hot water heating, provided the proportion is uniform throughout, as the temperature of the apparatus can always be carried as low as is required. By carrying a low temperature the heat given off is more mild and less uncomfortable to any one near a radiator.

A hot water heating apparatus, properly installed, will be found to be very economical and satisfactory.

Air In Hot Water Systems.

We wish to call attention, says the *Ironmonger* of London, to two causes of failure in hot water apparatus which, if peculiar, are not uncommon. The first is the existence of some water in a pipe or pipes when the proper filling or refilling is commenced. A hot water apparatus should be quite empty prior to its being first charged, or when at any subsequent time it is recharged with water. Then, if the cold supply is properly connected, the filling will proceed perfectly, and all air be expelled, as the water rises in the pipes. If, on the other hand, water is lying in any part of the apparatus, and more water is introduced, air will probably be locked between the two volumes of water. If all the pipes of a hot water apparatus were vertical, or could be given a really good rise or fall, the air, if imprisoned between two volumes of water, would work out; but with flat runs of pipe the air will be locked in and will remain in a very persistent and troublesome way.

To illustrate this let it be supposed that an apparatus has a dipped length in a horizontal flow or return main, as a result of the building settling or some other unforeseen cause. On testing, however, a leak is found which makes it necessary to empty the apparatus. In doing this the dip would remain filled, or partially filled, with water. On refilling this water would offer resistance to the free escape of air, and air would be locked in the pipe, and it might be in sufficient volume either to impair the circulation or even to stop it. There is nothing visible to indicate the cause of the trouble, and the fitter is puzzled to know why a main or branch which worked well on first charging and testing should fail to work after the apparatus has been emptied, for some trifling purpose, and recharged. Briefly stated it is essential that on filling an apparatus the water must enter at the lowest point, and as it flows in and rises up the pipes all air must rise easily and freely before it. If there is a dip to pass a door, then put either a small cock to drain it when the remainder of the apparatus is emptied; or, what is more usual, put an air vent on that side of it where the rising water reaches first. If there is any doubt, put an air vent on both sides. There must not be the slightest check to the free expulsion of all air from the pipes as the water enters them.

The second cause of failure is even simpler than the one just discussed. It is to omit to open all the air valves when charging. With many apparatus erected there is no trouble if the water is turned on and runs in with all air vents closed, for on subsequently opening them the imprisoned air comes away and water fills in everywhere.

On the other hand there are piping systems erected where this cannot be done, for the air cannot come away freely under these conditions. It should, therefore, be an invariable rule to have all air cocks open when charging. With a large apparatus this means having several hands to watch for the appearance of the water and immediately shut the cocks; but this involves but little time and expense, much less than would be entailed if a section became air locked.

HEATING HINDERED BY HELP.

BY LISTENER.

The chimney has come in for a great deal of discussion in the past, in connection with all kinds of heating and cooking apparatus, and as heating contractors

Heating Hindered by Help.—Fig. 1.—Plan Showing Chimney Connection.

become better informed, the important bearing which the chimney has on heating apparatus brings it still more attention in the discussions among the trade. It is probable that this will continue as long as men have to contend with chimneys and as long as the chimneys that have been constructed in old buildings exist without changes to meet modern requirements. It is perfectly natural that though the old buildings may continue in their old fashioned style, the occupants may have modern tastes and demand modern conveniences. This, in an instance that was recently brought to the attention of a boiler manufacturer, caused a complaint which he was expected to make good.

A boiler had been sold to supply a given amount of radiation, and one had been purchased which was rated

Fig. 2.—Elevation.

to have ample capacity to do the work with safety in the coldest weather, with still some reserve power. No complaint was heard from the apparatus until the cold period of February, when the complaint was made that the boiler did not keep the house warm. The heating contractor evidently had a generously disposed customer; and on the representation that such cold weather would tax the capacity of any boiler, he was induced to purchase another smaller boiler to be connected with the piping system, to help out the larger boiler in severe weather. After this boiler was set in position, instead of relief further trouble was experienced and led to a complaint being made to the manufacturers of the larger boiler, when the conditions were discovered as indicated by Fig. 1 in plan and Fig. 2 in elevation, which

show how the two boilers were connected with the chimney.

The first boiler was a large one and connected with the chimney by means of a 12-inch smoke pipe. When the smaller boiler was set in connection with it, an 8-inch pipe was connected by means of a Y into the side of this 12-inch pipe. The contractor evidently knew that this connection would be something of a handicap to the larger boiler and provided a vertical partition in the 12-inch pipe to separate to a certain extent the pipes from each other. Investigation proved that the chimney had two flues, and that at the point where the 12-inch pipe entered the chimney the partition had been broken away, so that the two flues were connected at the bottom. This could readily be seen by opening the clean-out door, which was placed a short distance below the pipe hole in the chimney.

Old chimney experts can readily understand what a handicap to the first boiler the pipe connection from the second boiler proved to be. It would have been far better to have left out the partition placed in the smoke pipe and to have increased the 12-inch pipe to a 14-inch pipe at the point where the 8-inch pipe was received. If it was not possible to have broken the partition between the two flues out of the chimney from the top to the bottom, it would have been far better to have connected one boiler with one flue and the other with the second flue. The first boiler set, it is claimed, would have had ample capacity for heating the building, had the chimney in the first place been of the proper size and construction; also that the money expended for the smaller boiler would have produced better results if it had been expended in getting the chimney into proper shape and size for the work that was required of it in operating the larger boiler efficiently.

The heating contractor often is severely handicapped when connecting furnaces or boilers with chimneys in old buildings. The owner will permit almost any kind of remodeling to be done in the cellar, but when he is asked to cut open the flues of the chimney from cellar to roof and to enlarge the size, he is very apt to turn his back on the maker of such a proposition in disgust and to listen favorably to some other contractor who is willing to attempt to heat the building without making such extensive changes on the different floors of the building as the construction of a proper chimney would necessitate.

Gast's Asbestos Air Cell Coverings.

F. J. Gast, 26 Cortlandt street, New York, is the manufacturer of Gast's asbestos air cell covering for hot air furnace pipes, furnaces, steam pipes, boilers, &c. One form of this material is put up in rolls of 250 square feet, it being 36 inches wide and $\frac{1}{2}$ inch thick. It consists of two thicknesses of sheet asbestos, one of which is plain or flat and the other corrugated, the two being cemented together to make a single sheet. When covering furnace pipes, for instance, it is wrapped around the pipe twice and fastened with iron or brass bands $\frac{3}{4}$ inch wide furnished for the purpose, or plain wire can be used. The same material is used on steam pipes. Another regular form of this material is made in sections 3 feet long by the manufacturer for 18 sizes of pipe, having a range of from $\frac{1}{2}$ to 12 inch diameters. He also furnishes molded fittings for elbows of various angles, tees, valves and crosses. It can likewise be made for pipes up to 24 inches diameter. Still another form is in the shape of blocks or boards for covering boilers, 6 inches wide and 36 inches long, or in boards 36 x 36 inches square. The thicknesses vary according to nature of the use for which it is intended.

DR. CHARLES J. SEARCH, 168 Putnam avenue, Brooklyn, N. Y., is the inventor of a Fire Pot for plumbers, using kerosene oil for a fuel. In its operation the heat of the burner vaporizes the oil so that it burns in the form of a gas, the flame of which gives off a very intense heat, which, it is claimed, can be easily regulated and is not easily affected by the wind.

HOT WATER OR STEAM.

In discussing the relative advantages of a steam or hot water heating plant a writer in the *Rays of Light* presents the following:

One of the points not credited to the water system is the fact that the hot water can be carried lower than the water line of a steam plant, which in many cases is a valuable point, as the boiler or heater can be located in one of the rooms to be warmed, thus saving all the heat that the fuel produces. The question is sometimes asked "Which is the better for heating apparatus, steam or hot water?" This question cannot be answered positively or in a word.

First, the matter of expenditure. The first cost of steam heating apparatus is somewhat less than that of hot water, owing to the fact that for hot water circulation larger pipes are required, especially for the returns; and also a larger amount of radiating surface is commonly, though not necessarily, used to compensate for the lower temperature at which hot water apparatus is usually operated. If the matter of first cost then is the most important factor, the decision must be in favor of steam.

On the other hand, the cost of fuel is an important consideration. This is in favor of hot water apparatus, especially where low temperatures are used. There are two reasons for this economy of fuel, the first being that in the fire box of a hot water boiler the products of combustion are in contact with the fire surface, which is at a temperature considerably lower than is the case when in contact with a similar surface of a steam boiler, say from 20 to 50 degrees less; from which it results that the products of combustion part with proportionally just so much more heat to the boiler, and are discharged into the chimney at a much lower temperature, with a corresponding less waste of heat. The second reason is that in consequence of the high specific heat of water, heat from the fire not immediately wanted can be stored up in the apparatus to be given out later as required, instead of being wasted in the chimney.

As to the danger of freezing, preference is to be given to a steam apparatus. It is undeniably true that if a hot water apparatus is neglected so that the fire is extinguished and any part of the apparatus is allowed to fall below 32 degrees F., such part of the system will be frozen and probably destroyed; and a similar result will happen if any radiator of such apparatus is entirely shut off and then exposed to extreme cold. This point militates against the use of a hot water apparatus in office buildings where part of the offices may be unoccupied, and so also in country houses, where indirect radiators which are thoughtlessly closed may be exposed all night to extremely cold weather; a hot water apparatus must be used with caution, while the steam system under similar conditions is less liable to freeze and break radiators.

If hot water be adopted it should not be forgotten that there is a justly raised objection to its use from the slow way in which radiators cool when shut off. The radiator is usually shut off when a room is too warm, and this is naturally just the time when it is desired to cool it quickest. Owing, however, to the high specific heat of water it takes an hour or two for it to drop to the temperature of the room, and heat thus retained gives annoyance or is wasted. If steam is used the radiators cool more quickly, for the steam in them is rapidly condensed and the only heat they hold is that of the iron, of which the specific heat is low compared with water; and all the radiating surface when shut off, therefore, ceases giving heat much more rapidly.

Hot water requires less skill and care in operation, as it dispenses with the gauge, gauge cocks, &c., and there is no water line in the boiler to be maintained or over pressure to be guarded against. In fact, the manipulation of a hot water boiler is almost exactly like that of a furnace. That is, if one wants more heat the fire is quickened, or if less heat is needed the draft is closed and the force of the fire checked. A hot water apparatus is usually left to the care of the ordinary house servant without apprehension of inconvenience or

danger. It should be said, however, that a steam apparatus is just as easily controlled after the person in charge has been instructed and cautioned.

BOILERS, RADIATORS AND VALVES.

The lull of the season with the steam fitters having been reached, it is a pleasure to note that the relations between the manufacturers and contractors during the year have been exceptionally satisfactory. Meetings of the manufacturers of heating boilers have been frequent and, notwithstanding the pressure that has been brought to bear at various times to effect an advance, prices have been maintained at one level throughout the year. This has been gratifying to the contractors who bid on work or architects' plans in the spring and had no difficulty in securing the goods to complete these contracts at the price on which their estimates were made. The confidence inspired among the manufacturers by their frequent meetings has enabled those who in the past have hesitated about piling up a large stock of boilers to run full during the dull season, and has led to a larger stock of goods being available this fall than has heretofore been the case. The result has been less difficulty in securing boilers by the contractors, and little inconvenience has been experienced through the scarcity of goods.

From such information as can be secured it would seem that the number of boilers sold this year is considerably in excess of that sold in any preceding year, which should mean that the manufacturer and steam fitter alike have benefited. A desire on the part of the manufacturers that the friendly relations of this year shall continue is evident from the fact that they are already on the alert to secure pig iron and material for next year at prices that will enable them to avoid any change in the present prices. At recent meetings a strong disposition to advance the price of boilers has been in evidence. Within the past month there has been an advance in pig iron, and there is no evidence that labor or any material which enters into the manufacture of boilers is likely to recede in price. With these facts in view the manufacturers have a problem to solve before they reach a decision as to whether or not the present prices shall hold or a change be made for the business of another year.

The steam fitter has had more trouble to secure radiation than to secure boilers, and it has been necessary in many instances to change from one style of radiation to another and to persuade customers to permit the change to be made. The rush of the season, however, has now been passed, and while shipments are still somewhat delayed any of the many styles of radiation can be secured with about the same degree of promptness. Apparently steam fitters have been more annoyed in securing the brass goods and valves needed on a heating plant than with any other of the materials needed. The manufacturers of the better class of goods have enjoyed an increased trade, and as a result steam fitters have constructed better work for their customers in many instances than they otherwise would.

The worry over the scarcity of small sizes of wrought iron pipe soon passed away when it became known that all the pipe needed was in stock, but that the jobbers had control of the available supply and had stiffened the price on account of the strike. At the present time the heating contractor can be reasonably sure of securing boilers, radiators, valves, pipe and fittings required for a heating system without experiencing any serious delay and at prices which are generally considered satisfactory.

The new plant of the Eastern Tube Company, at Zanesville, Ohio, is in partial operation, turning out 2 to 8 inch Tubes. It is expected that the entire establishment will be in full operation about February 1, when the company will be prepared to fill orders for Tubing from 1/2 to 16 inches in diameter. The officers of the company are: T. E. Beall, president; E. C. Card, treasurer; Joseph H. Beall, secretary, and C. A. Corbett, general manager. The main offices of the company are in the Bank of Savings Building, Pittsburgh.

New Quarters of the Frank C. McLain Company.

At the beginning of this week the Frank C. McLain Company transferred their offices and salesroom to their warehouse, on the corner of Thirty-eighth street and Eleventh avenue, New York. The main building is 60 x 110 feet. The shipping office is on the first floor, which is divided through the center so that on one side provision is made for the storage and handling of cast iron fittings. On the other side is a pipe shop, which is equipped with machines for cutting pipe of all sizes up to 8 inches, according to the sketch sent in by the customer. The front portion of the second floor will be used for the offices of the company and for displaying samples of their line of boilers, radiators and steam fitters' supplies. In the rear complete arrangements have been made for carrying a full line of malleable iron fittings. Another section is fitted for valves and brass work for steam fitters, while the further space on this floor will be devoted to the storage of hot water storage tanks and expansion tanks for hot water heating systems. The upper floors will be used for the storage of steam and hot water boiler sections and steam appliances.

The basement has one side equipped with special machines for assembling radiators of special sizes. This department has a capacity for storing 40,000 feet of radiation. The other side of the basement contains a steam boiler and engine, also a gas engine, either of which can be used for operating the pipe cutting and threading machines and the elevators. The balance of the cellar is devoted to the storage of the sections for the larger sizes of steam and hot water heating boilers. The building has ample floor space for carrying, in addition to the goods mentioned, a variety of pump governors, steam traps, pressure regulators, and the infinite variety of special appliances used in the modern heating plant which the company intend to carry in stock. Their facilities for handling orders promptly are increased by having in the rear of the warehouse a platform connected with a railroad switch and large enough to accommodate four cars. A special inclined trolley is provided for transferring goods from the cars to the building. Adjoining the railroad tracks, on one side, is a pipe storage shed, which is the full length of the platform, so that two cars may be unloaded in the shed at one time. Here it is intended to carry a large stock of black and galvanized iron pipe.

Pittsburgh Valve, Foundry & Construction Company.

The large new foundry being built by the Pittsburgh Valve, Foundry & Construction Company, at Twenty-sixth street and Allegheny Valley Railway, is rapidly nearing completion and will be occupied in a short time. This foundry is one of the largest in the Pittsburgh district, and is equipped with modern appliances throughout. It is the intention of the company to centralize their foundry operations in the new plant, and when it is ready for operation the foundries downtown, now connected with the Atwood & McCaffrey works and Shook-Anderson Mfg. Company and the foundry of A. Speer & Sons, will be abandoned. The Pittsburgh Valve, Foundry & Construction Company were organized about a year ago and issued capital stock to the amount of about \$1,150,000. G. E. Klingelhofer has retired as general manager and has been succeeded by C. R. Rhodes, formerly with the Shook-Anderson Mfg. Company. The new company acquired the plants of Atwood & McCaffrey, Pittsburgh Valve & Machine Company, Limited; Shook-Anderson Mfg. Company, the pipe fitting department of Wilson-Snyder Mfg. Company and the foundry of A. Speer & Sons. The officers of the concern are Henry M. Atwood, president; J. T. Speer, vice-president; C. A. Anderson, treasurer, and Moses Atwood, secretary and general sales agent. The company are engineers, founders, pipe fitters and machinists, and do a general business in steam piping for high pressure power plants. They also make all kinds of pipe, globe and gate valves, fittings and appliances for steam, water and hydraulic work.

New York City Notes.

Trade in general continues very good. Some plumbers are finishing up their old jobs, with only routine work ahead, but there are a number of new jobs about to be given out which will keep many busy all winter.

* * *

Among the new plumbing jobs now under way are an office building at 114 Liberty street, which is being done by John McMillan; a tenement at Seventy-eighth street and First avenue, by Joseph Bloch; a house at 8 West Fiftieth street, by J. P. Knight, and telephone buildings in West 124th street and East 124th street, by James Armstrong. Levins and Hannegan are busy with tenements in Mott street, Sullivan and Grand streets, West Thirty-ninth street and Tenth avenue.

* * *

The change in the city administration which will take place on January 1 will probably make many changes in those city departments with which the master plumbers do business. In addition to possible political changes, the new city charter changes many of the departments, as the Building, Sewer and Water Departments come under the control of each Borough President, with different rules probably obtaining in each borough.

* * *

The issuing of plumbers' licenses is a matter which has not been settled during the past four years, and which does not appear to be definitely fixed in the new charter. The Examining Board of Plumbers seems to be the most logical power to issue the licenses, as the body that makes a licensed plumber ought to have the power to take away his privileges when he violates rules or goes out of business.

* * *

Manhattan Branch are making great preparations for their annual entertainment and reception, to be held on Wednesday evening, December 18, at the Lexington Opera House. The Arrangement Committee, consisting of Messrs. Schnaier, Donohoe, E. J. Brady, Cummins and Boyd, with their associates, Messrs. Malcolm, J. W. O'Brien, Bryant, Tuomey, C. Tucker, I. J. Brown, J. F. Kelly, McCune, Hill and McQuillen, are sparing no efforts to make it the best in the history of the association. Tickets and boxes can be obtained from B. F. Donohoe, 1112 Park avenue, New York.

To Remove Scale from Boilers.

The use of soda for the removal of scale from boilers, says the *Decorators' Gazette and Plumbers' Review*, has long ago been advocated, and put into practice with varying results, depending, no doubt, upon the nature of the water into which it is introduced. Though it is now largely discredited in England, there are evidently still some who think it an efficacious solvent of scale, for, says a German contemporary, there is nothing more effective, and at the same time less expensive and easier to use, than soda; and that without analyzing the water used for the boilers. When filling the boiler add to the water so much dissolved soda that a strip of red litmus paper is distinctly, but not too much, blued. During working add regularly so much soda that the coloring of the paper faintly continues. In order to test the water blow off a little from the discharge cock, then shut it off so that only a few drops will run out, which, if allowed to drop on the litmus paper, should show the blue color in one or two minutes. Should this not take place, then more soda must be added, and, on the other hand, if the paper quickly shows a decided blue, no more soda must be put in. With a little experience it is easy to gauge the quantity of soda, and it will only be required to make tests once or twice a week. Soda prevents, or at least retards, the formation of hard scale, and more sediment is found instead. Old scale is also gradually loosened, and where it has been allowed to accumulate it is well to clean the boiler, when commencing the soda treatment, every two or three weeks. If there is no incrustation cleaning two or three times a year will be sufficient.

Heating and Plumbing Notes.

BURDETTE RAYNOR informs us that he has sold out his plumbing and heating business at Center Moriches, N. Y., and is about to open a shop in Southampton, L. I.

THE NORWALK HEATING & LIGHTING COMPANY of Norwalk, Conn., inform us that they are installing Kelsey Generators for heating the residences of William McMahon of South Norwalk and M. Willard, Spring Hill. They are installing a steam plant for B. F. De Klyn, using a Mercer Boiler, and are placing a large Gorton Boiler in the residence of W. P. Eno at Saugatuck, Conn.

T. J. CRONIN advises us that he has opened an office and branch of his plumbing business in Binghamton, N. Y., but that he will continue the shop at the old stand in Lestershire.

WILLIAM H. GORSLINE, president and treasurer of the Rochester Sewer Pipe Company and president of the New York State Sewer Pipe Company, died on November 9, at his home in Rochester, N. Y., aged 72 years.

THE GEORGE A. WEAVER COMPANY, Newport, R. I., have installed 12 Winchester Boilers during the past six weeks.

HENRY E. WEIBER of Kingston, N. Y., has been awarded the contract for installing the steam heating for the addition to the post office and custom house at Newport, R. I. His bid was \$1080.

JOHN E. JOHNS of West Scranton, Pa., has the contract for plumbing the West Side Hospital in that city.

FRANK N. SMITH, Susquehanna, Pa., a well-known plumber and tinsmith, died on November 3 from dropsy, aged 50 years. He is survived by a wife and five children.

JOHN T. SADLER, Elmira, N. Y., has the contract for the plumbing and gas fitting in the new Federal Building in that city.

ALBERT QUITTERFIELD and Homer Bruce, South Troy, N. Y., have been granted a patent for heating buildings.

HENRY BEUTELSPACHER, Bridgeport, Conn., has the contract for the copper work and steam piping on a new oyster steamer for H. J. Lewis & Co.

COCKRILL BROTHERS, Jackson, Tenn., have the contract for plumbing a large addition to the plant of the Southern Engine & Boiler Works at that place.

T. P. PERRY & SON, Ansonia, Conn., have the contract for plumbing and heating the new addition to the Hotel Dayton in that place.

E. W. PECK, Derby, Conn., is doing the plumbing in a parochial residence in that town in which three new bathrooms are being equipped with the latest improved fixtures.

SHUMWAY & RILEY, Northampton, Mass., are installing three Hot Air Furnaces in houses for James Reed, and are heating four houses for J. H. & W. E. Stetson with Furnaces.

EDWARD RADDING, Holyoke, Mass., is to erect an apartment house for 12 families which will have a modern system of heating and plumbing.

THE city of Manchester, N. H., has passed an ordinance creating a board for the examination of plumbers.

THE SPRINGFIELD FIRE & MARINE INSURANCE COMPANY of Springfield, Mass., are to erect a fine new building, to be equipped with a modern system of heating and plumbing.

THE CARMAN-THOMPSON COMPANY of Lewiston, Maine, have just received the contract for a steam heating plant for the new wing of the Insane Hospital at Augusta.

THE A. L. & E. F. GOSS COMPANY of Lewiston, Maine, have the contract for heating and plumbing the new Park street annex to the *Journal* Building in that place. They are also remodeling the plumbing in the Blanchard House.

THE Plumbing Board of Bay City, Mich., have organized, electing City Engineer George Turner as chairman and Health Officer Gilbert as secretary. Engineer Turner, Dr. Erwin and F. C. Finn have been appointed

a committee to draft rules on plumbing to govern the plumbers of the city.

THE plant of the Carnegie Tube Company, at Heidelberg, about 1 mile south of Carnegie, Pa., is approaching completion and is expected to be ready to begin operations by the first of the year.

J. W. CUTT & Co., Philadelphia, Pa., have the contract to install a low pressure steam heating plant in the Baptist Church, at Thirty-first and Diamond streets, in that city.

THE works of the Harrisburg Pipe & Pipe Bending Works, Harrisburg, Pa., are being run night and day. The Pipe mill, which has been idle for a short time for repairs, has been started up and will be run to its capacity. The Coil department is very busy.

THE plant of the Eastern Tube Company, at Zanesville, Ohio, whose offices are in Pittsburgh, recently shipped a consignment of Pipe to London, England.

THE offices of the National Tube Company will be removed from Conestoga Building and Empire Building to the Frick Building, Fifth avenue, Pittsburgh, when the latter structure is completed, about April 1, 1902.

MEMBERS of the Executive Committee of the Texas State Association of Master Plumbers have met the Attorney-General of the State, who recently brought suit against the members of the association on the ground of maintaining a trust. The result of this special meeting, which was designed to induce the Attorney-General to withdraw the suit, is unknown, as the Attorney-General has refused to make a statement.

THE Supervising Architect at Washington, D. C., will receive bids until November 29 for heating and ventilating the Post Office Building at Kansas City, Kan.

A RUMOR is current in the heating trade in New York that a new house will engage in the manufacture of heating boilers by the first of the year. The report has it that this house will be composed of two or three salesmen who are now engaged with the other boiler houses, and who are contributing to the success of these houses through their ability to sell goods. The enterprise is said to be backed by New York and Springfield, Mass., capitalists.

EDWARD LANDIS & BROTHERS, 609 North Ninth street, Reading, Pa., are doing the plumbing in 14 houses for Samuel Blatt, eight houses for Ebbert & Hain, seven houses for Francis Schide and six houses for S. Geho. They are also installing a steam heating system and doing the plumbing in Dr. E. Kiefer's residence, besides having a number of other contracts.

THE Board of Health of Buffalo, N. Y., have found objectionable features in the plumbing in the new terminal station of the International Traction Company, which they have ordered to be removed.

THE SMITH HARDWARE COMPANY, Hamilton, N. Y., have been awarded the contract to install the heating apparatus in the new Madison Union School in that town.

THE Board of Examining Plumbers of Grand Rapids, Mich., have decided that those master and journeyman plumbers who have been in business in the city for more than two years need not take the examination to secure a certificate of competency. They have also decided not to allow any applicant for a license to take the examination unless he has served an apprenticeship of five years, and that it shall not be necessary for more than one member of a firm to secure a license as a master plumber. In cases where a member of a firm desires to work it will be necessary for him also to take out a journeyman's license. Those who desire to work must obtain their certificate of competency and license before November 23.

THE ANDERSON COUPLING COMPANY, Portland, Conn., are putting on the market Anderson's Patented Lead Pipe Expanding Pliers, which, they claim, is the only tool ever produced that will turn out a collar on lead traps and lead pipes. In expanding the ends of the lead pipe by use of these Pliers there is no danger of stocking or bending the pipe, and the tool has been referred to as the "plumber's best friend." The price of this tool

is reasonable, and many of them are now in successful use.

SECRETARY GOMBERS of the National Association of Master Steam and Hot Water Fitters is renewing the interest of many members in the association by sending from the Wool Exchange Building, New York, with the compliments of the association, handsome engravings suitable for framing of "Watt's First Experiment," and as a companion piece the picture from *Life*, entitled "If James Watt Should Return to Earth." The pictures are accompanied by the Standard Flange Schedule of 1894 and the High Pressure Flange Schedule of 1901.

New Firms and Changes.

THE plumbing firm of Parsons & Newton, Stockbridge, Mass., have dissolved, and each member of the firm will engage in the same line of business for himself.

FRED. G. SEARLES has opened a plumbing shop in the Brainerd Building, at Mystic, Conn.

THE CRESCENT BRASS & IRON COMPANY and the Hart Company of Detroit, Mich., have been consolidated under the name of the Buckley-Hart Mfg. Company. The consolidated concern will continue to manufacture the same line of goods that have been made by the separate company—namely, Plumbers' Supplies, Lawn Sprinklers and Nozzles, Hardware Specialties, Brass and Bronze Vault Doors, Elevator Inclosures, Grills, Toy Banks, Furniture, Hardware, Bar Trimmings, &c.

A LETTER from David H. Murphy, one of the leading and best known plumbers of Marion, Ind., informs us that he has consolidated his business with John McDonald. The new firm are known as Murphy & McDonald. They will continue to do a plumbing, gas fitting and general jobbing business.

Stove Polishes.

Stove dealers frequently have a demand for stove polish of the same kind as they use. As the materials used in the making of stove and metal polishes are inexpensive, and as the machinery (if indeed machinery is required at all) is simple, and is adapted for hand power, the preparation of these indispensable articles of everyday use offers a legitimate field for the small manufacturer, as well as for the dealer who has sufficient space at his disposal in which to carry out small manufacturing processes of this nature.

Stove polishes, says a writer in the *Decorators' Gazette and Plumbers' Review* of London, are frequently referred to simply as "blacklead," a term which indicates sufficiently clearly their principal ingredient. Most of the black stove polishes are offered in the form of solid sticks, cubes, cakes, or balls, which are usually wrapped in paper, and often possess a highly glazed surface. The paste and liquid polishes are less used now than formerly, and are not wholly satisfactory, as it is exceedingly difficult to prepare a paste or a liquid from which the fluid medium will not rapidly evaporate. To the solid forms, therefore, attention will in the first place be directed.

The base of the ordinary solid black stove polish is blacklead, which is also known as plumbago and as graphite. In composition graphite is an impure variety of carbon. It is a mineral, and possesses a certain degree of metallic luster, which can be augmented by mechanical means after the substance has been powdered—a fact to which its utility as a metal polish is due. Graphite occurs in various parts of the globe in crystalline masses, and exhibits considerable variations in purity as well as in physical properties.

There are numerous uses in the arts and manufactures to which graphite is put. Among the chief of these are the manufacture of "lead" pencils, the manufacture of crucibles, retorts and other utensils used in dealing with refractory metals, the compounding of lubricants, and lastly in the branch of industry we are now dealing with—the preparation of black stove polishes.

Fine Cumberland graphite, of specific gravity 2.34 per cent., suitable for the making of pencils, contains (according to C. Mène) 91.5 per cent. of carbon and 7.3 per cent. of ash. Less pure varieties may contain from 80

to 70 per cent. of carbon, and from 11 to 20 per cent. of ash. It should be noted that as the carbon decreases the ash increases in quantity.

It is obvious from what has been said above that the various varieties of natural graphite will possess different values according to the purpose for which they are required.

For the purpose of making stove polish it is not permissible to use any graphite that may happen to come to hand. It is necessary to select the article with some care, and often to blend two or more grades together, in order to bring the product up to the desired standard. There are two points of pre-eminent importance in selecting graphite for stove polish making. One is the softness of the graphite; the other is its capacity to produce a highly lustrous surface after it has been reduced to a fine powder. It often happens that a sample of the native mineral exhibits one of these properties in a noticeable degree, and is lacking in the other; hence the buyer has to be on the alert, otherwise he may find that he must either turn out an inferior product, or that the expense involved in reducing the raw material to the proper degree of fineness is so great as to curtail in no small measure the profits of the manufacture.

The finest quality of graphite which is offered for sale in considerable quantities goes by the name of "Ceylon blacklead." Whether the whole of the material so designated is derived from the Ceylon mines is, perhaps, open to question, as the description has become, to some extent, a trade name for a somewhat hard but brilliant polishing graphite. Softer and more easily handled qualities are derived from Central Europe (Austria, Hungary, &c.), but these grades often, and indeed usually, lack high polishing properties, and must therefore be blended with a higher grade lead of the Ceylon variety. Large quantities of graphite are found in America, both in the United States and in Canada, and the material is excellently suited for stove polish making, as it combines the softness of the Continental grades with the luster of the Ceylon graphite. For this reason many American makes of stove polish are exceedingly difficult to beat in point of quality. An additional advantage secured by the American manufacturer consists in the fact that he is in a position to avail himself of the large quantity of "gas black" produced in the country. This material, besides possessing great staining properties which render it valuable as a paint pigment, is somewhat granular in texture, and is capable of taking on a certain degree of polish when rubbed. Hence when it is introduced as an ingredient of stove polish, it improves the color without injuring the polishing properties of the product.

The raw materials then with which the black stove polish maker starts are blackleads of varying grades, and American gas or carbon black. It is true that many makes, especially of the cheaper and commoner varieties, use other substances as well in their polishes. For example, water, glycerine, vinegar, acetic acid, sulphuric acid, green copperas, treacle, are specified in considerable quantities in many recipes. It is advisable, however, to limit the use of such assistants as much as possible, inasmuch as, although certain of them such as water and glycerine do not injure metal work, the majority are powerful corrosive agents, and the habitual use of polishes which contain them in considerable quantity is likely to result in damage to the metallic surface under treatment. It is often found that the graphite which is being used contains sufficient moisture and is of a sufficiently soft texture to enable the material to be molded with ease in the hydraulic press; on the other hand, it may happen that the material is somewhat dry and granular, and will not bind well, this being especially noticeable when a considerable proportion of carbon black has been added. In such cases the addition of a proportion of liquid binding material is necessary, and a mixture of water and glycerine will be the least hurtful to the metal. It will usually be found that the better and purer the quality of the raw material used, the less chemical matter is it necessary to introduce into the stove polish.

It is desirable now to consider the mechanical proc-

esses through which the raw materials pass in order to transform them into the finished and salable article. As a rule, three distinct operations are necessary. These are: 1, Powdering; 2, sifting; 3, pressing or molding. All grades of blacklead or graphite which are to be used for stove polish making must be reduced to as fine a state of division as possible, in order to obtain the maximum luster from the finished article. Only dry grinding methods are applicable in this case, as it has been found that if the graphite is ground in water it loses its luster. As a matter of fact, if so called blacklead powder is examined under the microscope, it will be found to consist of innumerable flakes or facets, the surface of which has become burnished by the powdering process. For this reason the ordinary edge runner mill has for long been considered the most suitable mechanism by which to effect the grinding. The runners should be stone—either granite or Derbyshire stone—and it is preferable to have the bed of the pan stone also, although it is quite permissible to have the latter of iron. The mill should not be too large, a diameter of 2 to 4 feet being ample in most cases. When very large mills are used, the powdered product is liable to be of extremely uneven composition, and the sifting process is thereby rendered more difficult. The proportion of water or glycerine which it may be considered necessary to add during powdering should be accurately judged, sufficient being added to prevent the material flying about in the form of dust, and not enough to cause the product to become pasty or to lose its luster.

The process of sifting follows on the powdering process. It is well known that the quality of stove polish depends largely on the smallness of the particles of which it is composed; therefore, as the grinding under the edge runner is certain to leave a proportion of particles of considerable size, it is necessary to remove these if a first rate article is required. It may be said at once that many stove polishes are made from materials that have not been sifted, and, of course, the necessity for this process will depend, to a great extent, on the care with which the powdering has been conducted, as well as on the quality of the article it is desired to produce.

There are various forms of sifters on the market. Among them are brush sifters, in which a spiral brush forces the small particles through a wire gauze screen; centrifugal sifters, in which the powdered material is inclosed in a wire gauze cylinder which is rapidly rotated, thereby causing the finer particles to escape; and vibrating sieves or riddles, which, although the simplest in their action, are suitable only for the separation of moderately coarse particles.

The presses and molding machines are so numerous in form that it is impossible within the limits of an article like the present to do more than simply refer to them. They vary not only in the mechanical devices adopted to produce the pressure, but also in their suitability for various classes of stove polish. There are hand presses actuated by a rack and pinion movement, by a lever, or by a screw; there are large power presses of varying construction, and there are numerous modifications of the hydraulic press.

The highly polished blackleads of to-day owe their brilliant luster in no small measure to the powerful presses now in vogue. Pressing and burnishing thus form one operation.

The following are selected recipes for cake blackleads, and may be taken as typical examples:

Fine Quality Dry Stove Polish.

	Parts.
Selected Ceylon graphite.....	100
American gas black.....	10
Acetic acid, diluted with an equal volume of water.....	2

Recipe No. 2.

	Parts.
Good Ceylon graphite.....	100
Austrian graphite.....	50
American gas black.....	5
Treacle	1
Glycerine, diluted with twice its bulk of water, a sufficiency.	

Recipe No. 3.

	Parts.
Good Ceylon graphite.....	100
Powdered ivory black.....	20
Green copperas.....	40
Glycerine, diluted with twice its bulk of water, a sufficiency.	

THE DAY CORNICE CLASS AT THE NEW YORK TRADE SCHOOL.

Owing to the excellent course of instruction given in the cornice and skylight class at the New York Trade School at Sixty-seventh street and First avenue, New York City, those young men who secure graduating certificates have not only acquired a considerable skill in the use of the tools and machines and in working sheet metal, but also have obtained a good mastery of pattern cutting. They are well prepared to enter upon the practical work of their trade, lacking only the experience gained from working in the shop and upon buildings. The evening class in this trade has been popular ever since it started, and on October 14 it opened practically full. Attention is specially called at this time to the day cornice class, which opens on December 9, so as to allow

The Day Cornice Class at the New York Trade School.

ample time for correspondence with the school to learn what is included in the exhaustive course of instruction given and the benefit to be derived from taking it.

The class is under the superintendence of William Neubecker, a practical cornice maker with a wide experience, who has superintended a large shop in which were constructed galvanized and copper cornices and skylights for some of the finest buildings in the vicinity of New York. After the pupils are taught the proper use of the hand tools—snips, soldering coppers, &c.—they are instructed in the operation of the various machines, including squaring shears, cornice brakes and circular molding machines. As soon as the first principles of the handicraft are mastered, the pupils are set to work making simple articles of sheet metal, similar to the small ornaments used on cornices. Instead of being given the pattern, or having the work cut out for them, as in the ordinary shop, they are given blue prints, drawn to various scales, of the different articles which they are to make. This system is followed up from the smaller pieces of work to window heads, bay windows, pediments, cornices, vases, and all the work which they do

during their stay at the school. From scale blue prints the pupils are required to develop patterns for the full size work, to cut it out, form it into shape and put it together. In some pieces of work three or four pupils are engaged and assist each other in its construction, attaching it, according to regular practice, to a brick or frame structure.

In the illustration presented herewith is shown an urn and pedestal, the joint work of two pupils of the day class of last year—M. Wolfstener of Washington, D. C., who made the urn, and B. Singer of Canton, Ohio, who made the pedestal. The base and cap molds of the pedestal were hammered up on a Robinson power circular molding machine, the fluted body being made by hand. The urn is entirely hand hammered work, made with the raising hammer on a raising block. The flutes on the top and bottom of the vase, including the circular ends, were made of zinc to avoid the scaling that would ensue from the use of galvanized steel. Four of the flutes were hammered up at one time and then dressed out smooth separately. The leaves at the top, which hold the acorn, were hammered up in the same manner as a circular molding and then cut out as required. The three flutes in the wing of the handle of the urn were hammered in one piece, while the edges of the handle were made from strips. As there are 16 flutes in the body of the urn, these flutes were fastened to 16 vertical sections of which it is composed.

This illustration of the work accomplished by students of the day class is presented to convey more clearly to the minds of those who may desire to take this course of instruction the proficiency acquired by those who give attention to their work while at the school. The New York Trade School has a thoroughly equipped shop, and in a few months the pupil is enabled to acquire both the handicraft and the knowledge of pattern cutting that can only be obtained in the ordinary way by the most studious application. Last year this class was patronized by only four pupils. Nevertheless the school authorities were willing to bear the expense attendant upon it. It would seem that such a valuable course of instruction is worthy of wider patronage, and we bring it to the attention of those who are interested in the cornice and skylight trade, so that a larger attendance may encourage the management of the school when the class opens on December 9.

International Tin Plate Corporation.

It is rumored that the American Tin Plate Company are negotiating for the purchase of the patents of the International Tin Plate Corporation, whose incorporation with a capital stock of \$125,000 was mentioned in our last issue. Whether or not the tin plate company will be successful in their effort is uncertain. It is understood, however, that those who are backing the new independent enterprise are unwilling to sell out their patents, believing that they have something that will enable them to compete successfully with the existing tin plate manufacturing interests. It is stated that the patents controlled by the International Tin Plate Corporation include the Allis-Andrews process for manufacturing tin plate. The claim is made that, by means of that process, the company will be enabled to turn out material at a much cheaper cost than can be done by the American Tin Plate Company under their processes; also that a better grade of plates can be produced. As mentioned in our last issue, the enterprise is being backed by substantial English capitalists, and it is contemplated to establish works not only in the United States, but also in Great Britain and Canada. Tests of the Allis-Andrews process made in Pittsburgh are said to have proved entirely successful. Report has it that the new enterprise will have a capital stock of about \$15,000,000.

THE work of enlarging the present large plant of the American Sheet Steel Company, at Vandergrift, Pa., by the addition of nine new mills, is progressing, and it is expected that the new mills will be ready for operation early next year.

Sheet Metal Monuments.

BY WILLIAM NEUBECKER.

A branch of sheet metal work to which little attention is given, except by those who make a specialty of it, is that of galvanized sheet metal monuments. When well painted in imitation of marble or granite the difference can hardly be detected. A monument which has been painted with three coats of metallic paint inside and outside and then the desired imitation on the outside will endure for years before any defect by rust would be noticed. In the accompanying illustrations are shown various designs and methods of construction, which may be interesting to those who contemplate doing work of this kind. There is no limit to the number of styles which can be gotten up, using a little judgment and study. In Fig. 1 is shown a simple form, with semi-circular top, A showing the front view and B the side, the front corners being broken, as indicated by C in side view. Diagram D shows a section through X Y, and shows how the corners are soldered, the raw edge at first and then the cove E set in afterward. It is sometimes the case that the base and slab are made in two sections, then the base is formed as at F and the slab H set into it and soldered around at the joint indicated by the arrow. Diagram K shows how the base is sometimes stiffened by inserting a joist, as at J. When soldering the back to the return strip, B in side view, the joint

Fig. 1.—A Simple Form of Monument.

at the corner is made as shown in diagram L, the top or return strip is run through the thick edge machine, making a convex bead, while the back is run through the same machine, forming a concave bead; they are then placed in position, as shown, and floated with solder.

In Fig. 2 is shown another form of monument having a raised panel. A shows the front and B the side. A raised ornament or head can be placed at C, which is shown in section by D; the front face has a raised scroll, E, on each side, shown in section by F. When forming the front the panel should be formed onto it in one piece, as shown by the section (taken through H I) at L M J K, on which it will be noticed that the return strips have the thick edge or bead, as described in Fig. 1. By forming the panel as shown by J K in Fig. 2 we place the seams or miters connecting with the base and top at X X X X in front view. This avoids buckles, which would be apt to appear if the panel were soldered on separate. On this raised panel on front it is usual to place a name or date, which is accomplished by buying letters and figures cast of lead with or without beveled edges. These letters can be obtained in any size, from 1 to 6 inches, but when fastened to the panel they must not be soldered on the outside, as that would spoil the outline of the letter, they being soldered from the inside as follows: Having decided what name and date shall be placed on the panel, pencil lines are marked upon the panel, and the letters placed in their proper position, as, for example, E in diagram O. Scribe a pencil line around this letter, which, when the letter is removed, will look like E in diagram R. Then by means of the

rivet punch punch two holes, as shown by the arrow points in diagram S.

The letters or figures are now held carefully in position on the outside and soldered from the inside by means of soaking the back of the letters or figures through the small holes previously punched into the face of the panel, as is better indicated in diagram T, in which T shows the panel face, with the hole punched in same at U, while the letter V is held in its proper position and soldered at Y, on the inside.

In Fig. 3 is shown another style of monument a little more elaborate, a front and side view being shown; in the flat space A any name can be placed, while at B and C round columns are inserted of style similar to B. C shows how the monument is finished first and the column placed in afterward. When setting on the circular mold D E care should be taken to have the flat surface F D F in one piece, and not solder the semicircular piece D, as shown by the dotted line, as that seam would always show. In diagram F is shown an enlarged section through D E, showing how the circular faces are stripped square and then the cove H set in afterward, then mitered with the horizontal molding in the front view.

Fig. 4 shows an elevation of a square shaft with broken corners; the joints at A, B and C are constructed

Fig. 2.—Another Form of Monument Having Raised Panel.

SHEET METAL MONUMENTS.

in a manner similar to that shown at H in Fig. 1, while the name, which would be placed at E in Fig. 4, is fastened as explained in Fig. 2. When fastening metal monuments wood bracing is let into the ground, over which the metal work is placed in sections, well braced, then soldered.

It is sometimes the case that the base of an old stone monument can be used on which to fasten the metal base, as indicated in Fig. 5, in which A represents the stone base, having a groove cut into same, as at C, into which the base B, having an edge bent on same as at X, is placed; it is then calked with molten lead, which secures the metal base; of course, additional bracing must be placed on the inside. In many cases a cast iron base or curb is placed into the ground, as indicated at A in Fig. 6; the metal base B, which is made of No. 20 galvanized sheet iron, is then bent in the manner shown, and bolted to the cast iron curb by the round headed bolts C fastening on the inside by the nut D, the inside band iron brace E resting on the curb C at F.

THE CLASON ARCHITECTURAL METAL WORKS, Providence, R. I., are now operating their new factory on Kinsley avenue, which is well equipped for turning out a large variety of metal work. We are advised that this concern are executing an extensive order for fire proof Metal Book Stacks for the Sayles Library, Pawtucket, R. I., and are also engaged on a number of important contracts for Skylights, Metal Window Frames and Cornices, and are making a lot of large Copper Revolving Ventilators with cowls, for a public institution.

The Tin Mill Wage Scale.

The tin mill lodges of the Amalgamated Association are now voting on the proposition to continue for three years the wage settlement made with the American Tin Plate Company in New York in September. It is understood that those lodges that have already voted are favorable to the proposition. A number of the lodges, however, are holding back their vote. The Amalgamated Association have until December 14 to send in their decision on the matter. So far as the workmen in the mills that are recognized by the American Tin Plate Company as union are concerned, the proposition is a good one, as it secures to them good wages and steady work for three years to come. The only drawback to the arrangement, from the point of view of the union workers, is that it does not include a number of the mills which were formerly recognized as union works. Should the vote of the Amalgamated lodges be unfavorable the present wage agreement will expire at the end of a year from the date of its signature.

Coating Terne Plates.

A correspondent of the *Decorators' Gazette and Plumbers' Review* of London received the following in answer

Fig. 3.—A More Elaborate Style of Monument.

Fig. 4.—Elevation of a Square Shaft.

Fig. 6.—Joining a Metal to a Cast Iron Base.

Fig. 5.—Fastening a Metal to a Stone Base.

SHEET METAL MONUMENTS.

to a request for assistance in coating sheet iron so that vessels made of it could withstand the action of sulphuric acid:

The terne coating you are using—90 per cent. lead and 5 per cent. tin—is excellent, but, of course, a good deal depends upon the dipping, and for many purposes you could safely reduce the tin by half, bringing it to 2½ per cent. As far as sulphuric acid is concerned, try using pure lead alone, but the dipping process would have to be remarkably well done for it to stand. You should particularly test your marine acid (HCl) for selenium with a crystal or two of sulphite of soda, and reject if it gives a brick red precipitate. The merest trace plays perfect havoc with the dipping. But even with all care it is a question which can only be tested by direct experiment, and very doubtful in regard to the result. Moreover, while it might stand acid of one strength, say concentrated, it might not stand weaker acid, say chamber acid. The latter often contains nitrous acid, as it comes from the chambers, and that eats the body out of anything. We presume CO₂ is a clerical error for SO₂. The latter we should think worse than the sulphuric acid itself. If they are able to get a coating to stand they would revolutionize the whole acid trade and do away with carboys. Can they not get some Sheffield acid maker to work in concert with them, and test their casks with acid of different strengths against (a) pure lead, (b) ½ per cent. tin, (c) ¼, (d) 1 per cent., (e) 1¼, (f) 1½, and so on, up to 5 per cent. of tin? The writer found that even ¼ per cent. of tin enabled the “lead tinned” drum to withstand “turps.”

ROLLING MILL MACHINERY CONSOLIDATION COMPLETED.

At Pittsburgh last week deeds were filed by which the United Engineering & Foundry Company, organized in that city several months since, acquired title to the properties of the Frank-Kneeland Machine Company and the Lincoln Foundry Company. The property of the Frank-Kneeland Machine Company is located at Fifty-fourth street and Allegheny Valley Railway and includes 4¾ acres, on which are erected large foundries and machine shops. The price paid by the United Engineering & Foundry Company for this property is given in the deed as \$175,000. The property of the Lincoln Foundry Company is located at Sixty-first street and Allegheny Valley Railway and contains about 4 acres, on which are also erected foundries and machine shops. The price paid for this plant was \$160,000. These two concerns were taken over by the United Engineering & Foundry

Company at the time they were organized, but the deeds to the properties have just been filed in the courts.

In addition to these two concerns the United Engineering & Foundry Company also took over the Lloyd-Booth Company of Youngstown, Ohio, and McGill & Co., whose works are at Twenty-seventh and Smallman streets, Pittsburgh. The main plant of the United Engineering & Foundry Company will be located at Fifty-fourth street, where all kinds of rolling mill machinery, including shears, tin plate and sheet mills, will be built. The plant of the Lincoln Foundry Company will remain where it is and will be devoted exclusively to the manufacture of rolls. It is probable the plant of the Lloyd-Booth Company will be materially enlarged. It will be devoted to the manufacture of rolling mill machinery and rolls, and is one of the largest and most valuable plants owned by the United Engineering & Foundry Company.

The officials of the concern are: Isaac W. Frank, president; Charles H. Booth, first vice-president; Fred. A. Campbell, second vice-president; Edward Kneeland, treasurer, and Charles A. Satler, secretary. The Board of Directors consists of Isaac W. Frank, Otis H. Childs, Thos. J. Bray, Jr., Lloyd Booth, Edward Kneeland, Charles H. Booth, Fred. A. Campbell, J. J. Donnell, James H. Lockhart, Richard Garlick, W. L. Abbott and Charles E. Satler.

FLASHINGS.

THE YOUNGSTOWN IRON, SHEET & TUBE COMPANY of Youngstown, Ohio, have closed a deal for the purchase of the New Process Galvanizing Works recently established at Niles, Ohio. It is understood that the galvanizing plant will be removed to Youngstown and added to the large plant that the Youngstown company are now constructing in that city.

It is rumored that the American Tin Plate Company contemplate the gradual abandonment of the old system of manufacturing Tin Plate, and the introduction of the Monessen system at all their works. Should this plan be carried out it will involve a considerable reduction in the number of Tin mill workers from those now employed at the various plants of the American Tin Plate Company.

PRESIDENT T. J. SHAFFER of the Amalgamated Association has sent out a circular to the officers of the various Tin Plate lodges of the association, denying the report that the workmen of the Star and Monongahela Tin Plate mills in Pittsburgh were organizing lodges independent of the Amalgamated Association.

Work is being pushed as rapidly as possible on the new Tin Plate plant of the Jackson Iron & Tin Plate Company, Clarksburg, W. Va. The mill building will be of steel construction, 150 x 350 feet in size, with a railroad track running the entire length of the building. The necessary machinery is now being installed. The company have let the contract for the erection of a water tower with a capacity of 40,000 gallons, for the protection of the plant from fire. The erection of the plant is proceeding under the direction of C. C. Moore, general manager, and William Collier, superintendent of the company. It is expected that everything will be completed and in running order by or soon after January 1.

GROUND was broken last week for the erection of a new Tin Plate plant at McKeesport, Pa. It is stated that the new works will be a ten-mill plant, giving employment to about 700 men and having a capacity of 40,000 boxes of finished Plates per month. The plant is to be located on the Port Vue side of the Youghiogheny River, opposite McKeesport.

THE corrugating plant at the Laughlin Sheet mill plant, at Wheeling, W. V., was started last week, and it is expected that two of the new Sheet mills will be put in operation within a week or so.

NOHSEY & SCHWAB have now entered upon the occupancy of the ground floor of a new building erected at 412 to 416 Second street, Memphis, Tenn., which has been designed and especially fitted up for their class of work. The floor is 100 x 65 feet. The firm have a large amount of business on hand. They have contracted to do the whole of the Tin and Galvanized Iron work on a new hotel that is being built at Clarksville, Miss., and are also doing the Slate and Tin work on the Court House, at Tunica, Miss., and the Sheet Metal work on the Memphis Light & Power Company's office. They have just completed the Tin Roofing on the grand stand of the Memphis Trotting Association.

On the evening of Saturday last the clerical force of the St. Louis branch of the Berger Mfg. Company enjoyed a dinner in the banquet hall of the Planters' Hotel, through the hospitality of S. Y. Buckman, manager of the branch. The affair was the occasion for several good speeches, among the speakers being Messrs. Buckman and Burton. Mr. Buckman touched upon the company's policy and business methods, and commended the personal application shown in the various departments of the concern. His remarks were peculiarly appreciated, displaying as they did the thorough good fellowship and understanding which exists among the company's employees. This topic of *bon camaraderie* was also referred to by Mr. Burton, who commended highly the company's policy, methods, &c., and advanced the assertion that strikes and disputes would soon be things of the past if other manufacturers were as liberal and fair minded in their methods.

A NOTABLE feature in the Tin Plate industry of South Wales, says the *Iron and Coal Trades Review* of London recently, has been the restarting of so many works, some

of them after years of idleness. At the end of September there were 377 Tin Plate mills at work, as compared with 349 mills working at the end of August. Thus there has been an increase of 28 mills in the course of one month. These 28 mills would have a producing capacity of about 15,500 boxes per week. As compared with a year ago, however, the increase has only been 18 mills, the figures being 377 and 359 respectively. There are at present 60 idle mills. In September the total exports of Tin Plates and Black Plates amounted to 29,745 tons, and in August they were 25,684 tons, or an increase for September of 4061 tons.

At the Curtis Sheet mill at Zanesville, Ohio, two mills have been started up and are working smoothly. The other two mills are expected to be put in operation by December 1.

THE building of the new Sheet mill of the Sharon Steel Company, Sharon, Pa., has been delayed somewhat by the inability of the company to obtain sufficient supplies of structural material. Work on the new plant, however, is being pushed as rapidly as possible, and it is expected that it will be in operation in the early part of next year.

THE AMERICAN TIN PLATE COMPANY have sold what remains of their plant at Blairsville, Pa., to the Columbia Plate Glass Company. The old Tin Plate mills will be torn down and removed to some other location.

H. J. PRATT & Co., Springfield, Mass., have completed the Sheet Metal work on one large building for J. Cooley, and are about engaging on the Metal Work on another block of similar character.

THE Master Tinnners' Association of Memphis, Tenn., have been incorporated by Henry Tohsey, Jacob H. Schwarzenberg, Charles Wesendorf, D. Lineham and A. W. Burdick.

THE LALANCE & GROSJEAN MFG. COMPANY will shortly put into operation the foundry, 50 x 90 feet, which has been in course of erection at the company's Tin Plate works at Harrisburg, Pa. There will be two cupolas.

NEARLY all the contracts for the new plant of the Rolling Mill Company of America to be erected at South Counellsville, Pa., have been placed and excavating for the new building has been started. The initial plant will consist of six Sheet mills, but the buildings will be laid out with a view of making it a 20-mill plant in the future.

CHARLES E. POPE of Charles E. Pope & Co., Iron and Steel factors, of Pittsburgh, and also president of the Pope Tin Plate Company of that city, has gone to California to recuperate his health.

THE report that some new mills will be added to the Wellsville Works of the American Sheet Steel Company, Wellsville, Ohio, is incorrect. Ground has been broken for the bed plate of a large new engine to be installed, from William Tod Company, Youngstown, Ohio, and this probably gave rise to the report that some new mills would be added.

THE MANOGUE-PIDGEON IRON COMPANY, Memphis, Tenn., importers and jobbers of Steel, Railway Supplies and Tin Plates, owing to the great increase in business have recently enlarged their main storehouse building by a brick addition, which will double their storage capacity.

THE Sheet mill plant of the American Sheet Steel Company, at Dennison, Ohio, which was closed temporarily on account of the scarcity of Billets, is again in full operation.

THE MAX AMS MACHINE COMPANY, 372-374 Greenwich street, New York City, are about to erect a machine shop at Hoboken, N. J., for the manufacture of Canning Machinery as applied to a new method of making Solderless Sanitary Cans. Plans for the buildings have just been completed and the matter of equipment is about to be considered.

E. VAN NOORDEN COMPANY, 944 Massachusetts avenue, Boston, Mass., are sending out their Catalogue B, which describes in detail Skylights, Ventilators and Sheet Metal Work of Galvanized Iron or Sheet Copper for all kinds of buildings, in the construction of which

they have had 25 years' experience. They also manufacture Roofing, Gutters, Conductors, Shingles and Corrugated Iron for roofs and siding, metal windows and light iron buildings.

HUBBARD & Co., manufacturers of Shovels and Railroad Tools, are erecting a Sheet plant near their present works, at Sixty-second and Butler streets, Pittsburgh. The scarcity of Sheets and the consequent inconvenience and delay experienced in securing a sufficient supply for their manufacturing purposes have induced the company to enter upon the production of their own material. Plans have been prepared for two 22-inch mills, work upon which will be begun shortly. The plant will be located on the river front, east of the present works of the concern, and will be completed and ready for operation in February. The company will buy their own Sheet Bars to begin with, but later on may install open hearth furnaces and Bar mills.

AN American patent has been granted to Heinrich Wachwitz of Nuremberg, Bavaria, for a method of metal welding which consists in a process for plating Aluminum Sheets with copper or other metals. The process consists of applying to the surface of the coating metal, by hammering, a thin layer of aluminum, then applying the compound Sheet to the Aluminum Sheet or body to be coat-

enabling the sheet to be easily and quickly entered and retained in the groove; also that the beading rod adjusts itself right side up without any assistance from the operator.

The process of forming a length of gutter is thus practically a continuous operation, very simple and easily performed by unskilled labor. First, the strip of sheet metal is entered into the beading rod groove, and the rod given one revolution which forms the round bead on one edge of the gutter. Then, without changing any crank or making any adjustments, the operators grasp the forcing bar handles and swing it forward, partly around the forming roll, and back again onto its supports. The loose beading crank rod is then removed and the completed gutter is slid off the machine. The mechanism is arranged to allow the gutter to be drawn off from either end of the machine, enabling the machine to be set in the shop more conveniently for both light and space.

In operating the machine the beading rod is not withdrawn, and only one crank is removed, which is the only change or adjustment necessary to form the completed gutter. The only adjustments required are when changing the machine to form a different sized gutter. The capacity of the machine is stated to be from 600 to

The Electric City Gutter Former.

ed, and heating, rolling and working the same together. Sheets plated by the Wachwitz process are being manufactured in Germany and are said to be used for many purposes with success. It is understood that steps are to be taken to manufacture these Sheets in the United States.

W. A. GRODT, dealer in Tinware, Pumps and Fittings, has removed from Birmingham, Ala., to Frankfort, Kan., where he will make a specialty of Roofing and Cornice Work.

The Electric City Gutter Former.

The Double Truss Cornice Brake Company, Buffalo, N. Y., have just put on the market the Electric City Gutter Former, herewith illustrated. It is designed for forming the usual half round eave gutter in long lengths, with a round bead on one or both edges, and with either lap or slip joint as desired. The machine is referred to as being constructed and operated on an entirely new principle, different from any device ever produced for forming long length gutters. In devising the machine the makers state that they have overcome the weak points usually found in machines for doing this class of work. There are end journals and cranks on the forming rolls, but the rolls are secured rigidly to the bed piece of the machine at intervals along their entire length, and bend the material around the rolls with a "mechanical forcing bar," which is also secured to the bed piece at intervals along its entire length. This arrangement, it is explained, prevents any possibility of either the material or forming rolls springing in the center. The forcing bar, it is pointed out, applies a perfectly even tension, or pressure, against the material being formed throughout its entire length, insuring a perfectly straight and evenly formed gutter, each piece uniform in size and shape with the other, requiring no reforming or pressing into shape with the hands. The sheet metal is entered into the beading rod groove in an upright position, the weight of the metal, it is shown,

1000 feet of perfectly formed gutter per hour, according to the skill of the operator and the grade of material being formed.

Curious Products in Brass Wire.

Among the curiosities of Birmingham industry, according to an English contemporary, few are more remarkable and interesting than some branches of the brass wire trade. No inconsiderable quantity of the brass wire made in Birmingham finds its way to Old Calabar, on the Gold Coast of Africa, in the form of guinea rods, 3 feet in length, 100 of which form a medium of exchange for palm oil among the natives, representing to them the equivalent of the English guinea. Some years ago it was not uncommon for orders to reach Birmingham for these guinea rods to the extent of 20 tons each. Zanzibar takes large quantities of brass wire in coils. The native artisans at Unyanyembe convert the wire into coil bracelets, a ring of wire being sufficient to make two or three of the ornaments, each weighing about 3 pounds. From the Zambesi and other parts of Central Africa the demand is for heavier coils, the brass bangles worn by the natives averaging 4½ pounds each. In addition to rings of brass wire, large quantities of armlet and anklet rings, made of tube from 2¾ to 4 inches in diameter, are made in Birmingham for Central Africa. These rings, when "milled," burnished and lacquered, are used by merchants on the Gold Coast for payment of debts and exchanges with the natives, who bring down palm oil and other products, receiving the rings in barter. A single order received in Birmingham 25 years ago included 240,000 of these rings, 3½ inches in diameter, weighing, all told, over 23 tons!

It is announced that Andrew Carnegie has given the sum of \$500,000 to build and equip a technical college in Southern Scotland. The institution, it is said, will probably be located at Galashiels, in the County of Roxburgh.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

DETAILS OF AN UPRIGHT DRAWING BOARD.

From W. B., Philadelphia, Pa.—Kindly inform me through the columns of *The Metal Worker* how the straight edge on an upright drawing board is operated. By what mechanical device in the back of the board can it be moved up and down?

Answer.—There are several methods of accomplishing what our correspondent asks for, though the necessary mechanism is not usually placed at the back of the board. Whatever be the method employed it is evident both freedom and accuracy of movement must be insured in order that all lines drawn along its edge shall be exactly parallel. These results can perhaps be most perfectly and simply accomplished by the design shown in Fig. 1 of the accompanying illustrations, which will

Fig. 1.—General View of Upright Drawing Table, with Movable Straight Edge.

the straight edge, running its entire length, upon which drawing instruments, &c., may be laid. The difficulty may be entirely overcome, though at greater expense, by placing another shaft and sprockets against the lower edge of the board, and, discarding the counterweights, passing the chains around the lower pair of wheels back to the straight edge, where they may be attached in such a manner as to take up any slack.

Instead of the sprocket wheels, flanged drums, such as shown at A, may be substituted at the ends of the shafting, around which is wound metallic tape in place of the chains. For this purpose the tape must be in two pieces at each end of the board. The piece which is attached to the straight edge at its lower end must be firmly attached at its upper end into one channel of the drum, while the other piece of tape is similarly fixed at its upper end in the other channel of the drum, its lower end being attached to the counterweight. Thus as one piece of the tape at each end of the board is being wound up by the upward movement of the straight edge the other piece is being unwound by the counterweight, and both being attached to the drum neither can slip.

The drawing board is usually suspended from the upper beam of the frame work by means of ropes attached to it at the back, which pass over pulleys, as shown, to counterweights behind. This permits the entire board with its attachments being raised or lowered at pleasure, the board being kept in a horizontal position

Fig. 2.—Drawing Board, with Movable Straight Edge Operated by Means of Cords and Pulleys.

DETAILS OF AN UPRIGHT DRAWING BOARD.

require very little explanation. A pair of bearings are screwed to the top edge of the board, through which passes a rod or piece of small shafting, running the entire length of the board and extending sufficiently beyond at each end to receive a pair of sprocket wheels. Chain belts are attached to each end of the movable straight edge and are passed over the sprocket wheels and attached to a pair of counterweights sufficiently heavy to balance the weight of the straight edge when at the position most used. As both sprockets are firmly keyed to the shaft, any movement at one end of the straight edge insures an equal amount of motion at the other. Sprocket wheels and chains of the type used on bicycles will be satisfactory for the purpose, though chains of lighter weight, if constructed without play, will perhaps be more desirable. A small clip or slide fixed to the projecting ends of the straight edge at the back and passing behind or under the edges of the board will prevent the straight edge from lifting away from the face of the board.

As in the upward movement of the straight edge the chain is being passed over the wheels, some weight is being constantly transferred from the near side to the further side of the wheels. This would have a tendency to prevent the straight edge remaining at rest when at any position other than that near which the counterweights have been adjusted. As it is usual to incline the board somewhat, as shown in the figure, this difficulty is in part overcome by friction. With this in view it is customary to sometimes attach a tray or projecting shelf to

by means of cleats on the back, which slide against the sides of the inclined beams.

The parallel movement of the straight edge may also be accomplished by means of cords passing around a system of pulleys attached at the corners of the board, as shown in Fig. 2. This method is adaptable to boards of smaller size and is more liable to error on account of the stretching of the cords. If, however, very fine woven cord and smoothly running pulleys be used good results can be obtained. The cords are crossed at the top of the board, as shown in the top view. Thus the cord which is attached to the upper edge of the straight edge at the right end passes over the near pulley at the upper right hand corner of the board and over the further pulley at the upper left corner and thence down and around the lower pulley at the left side and is then fastened to the lower edge of the straight edge. If the direction of movement be followed along this cord, as indicated by the arrows, it will be seen that a downward movement of the straight edge at its right end will cause a movement in the same direction at the left. In the same manner an upward movement at the right would be transmitted to the opposite end through the other cord. The lower pulleys should be attached to the edges of the board by screws passing through slotted holes so that any slack in the cords occasioned by usage can be taken up.

Other methods, such as a rack and pinion movement, also a pair of levers crossed and working between the lower edge of the straight edge and a projecting strip on the lower edge of the board, have been used.

BACK DRAFT FROM CHIMNEY.

From Y. K., Pennsylvania.—I am having trouble with a chimney in a summer residence which has a large fire place at the bottom, used to burn regular cord wood 4 feet long. The wood is burned in a large open fire place in the living room, being laid on a set of fire dogs. The chimney has three flues in it, the flue in question, which is the middle one, being 18 inches square. The two side flues are 14 x 18 inches in size and are used in connection with fire places in chambers on the second floor. Each flue is separate and has no connection with the other, all leading directly from the fire places to the top of the chimney. The chimney acts in this way on any kind of a windy day, particularly when it blows from the northeast, north or northwest. The down draft blows the smoke into the large living room, so that the people must either stop the fire or open the windows to

Back Draft from Chimney.

allow the smoke to escape. I have been advised to close the top of the chimney somewhat to check the down draft, but instead of making it better it acts worse. The top of the chimney is covered by a large slate with openings at the top of the flue 12 inches high. The sketch given herewith will give an idea of the location of the chimney and its construction.

Note.—This is the season of the year when our readers are frequently called upon to overcome chimney troubles, and some of them can doubtless solve this problem without difficulty. It would seem that the trouble is due to the slate cover being placed too near the top of the chimney. The chimney, having an area of 18 inches square at the outlet, is cut down to a space 18 inches wide and 12 inches high, or reduced about one-third, by the slate cover. A simple remedy would be to remove the stone cap and watch the result. If it proved beneficial, and if it is necessary to use a cap to prevent rain and snow coming down the chimney, the supports to this cap should be elevated so that the openings in the side will be 18 or 20 inches high. If this is done, it is doubtful if the wind will drive the rising smoke down the chimney, but will rather blow it all out through the openings.

CONSTRUCTING A CHURCH FURNACE.

From Royal Heating Company, San Francisco, Cal.—Replying to the inquiry of your correspondent, "A. S.", in *The Metal Worker* of November 2, regarding the heating of his church, we would say that he can do the work in good shape with a 50-inch box stove, if he puts a good drum or radiator on the stove, and if the church is well built. We would advise the use of one 27 x 27 inch or 30 x 30 inch register face each for hot air pipe and a cold air return from the room to the heater so as to circulate the air. These two register faces should be placed together, right in front of the seats. Our experi-

ence has been that it does not make a particle of difference where the hot air enters a room, especially if there is a return pipe to the furnace. The Sunday school room can be heated by taking the hot air out of the top of the furnace, and taking the cold air from the floor of the room back into the furnace. There should also be provision for taking cold air from out of doors, so that when the church is warm and is occupied by the congregation fresh air will be introduced into the room.

We have just completed a job where we have used one register in a church, 40 x 60 feet in size, and we guaranteed that the variation in temperature should not exceed 5 degrees on four thermometers placed in the four corners of the room. Upon actual test, the variation was 2 degrees. We have another job in this city where we are warming one room, the floor level of which is 30 inches below that on which the furnace rests, but we exhaust the air from the floor level of the room we are heating, and discharge hot air into it near the ceiling. We have a number of jobs of fine work, where we take one large main pipe from the heater and have from six to ten branches running off from it.

TRADE NOTES.

THE NEW YORK ALUMINUM COMPANY, 142 Worth street, New York, have organized with the following officers: President, Herman Behlen; vice-president, August M. Kehn; secretary-treasurer, C. Pilz, and manager, William Gottlob.

THE UNITED STATES LAMP & STAMPING COMPANY recently organized at Moundsville, W. Va., with a capital of \$100,000, are about to erect a factory building in which they will employ 250 workmen. The directors of the new company are: Albert Schenk, Louis Stone, G. A. Wencher, C. W. Stewart, C. A. Weaver and J. N. Sanders.

THE HILL, WHITNEY & WOOD COMPANY, formerly of Waltham, Mass., have changed their firm name to the United States Aluminum Company, and their location to Pittsburgh, Pa. The company do work of all kinds in Aluminum.

THE GRIEVER & TWAITS COMPANY, Cincinnati, Ohio, manufacturers of Ornamental Wrought Iron and Metallic Art Goods, will be in the market for Power Presses, Power Riveters, Power Punches, Power Shears, Poppet Drop Hammers, Scroll Saws, Leather Belting, Hangers and Shafting, complete Plating Outfit, and entire equipment for gas producing plant, as soon as the new plant they are building at Indianapolis, Ind., is ready for occupancy. The company expect to move to their new location March 1, 1902.

THE OHIO GALVANIZING & MACHINE COMPANY have let contracts for the erection of their new plant at Niles, Ohio. The main building will be 50 x 200 feet.

THE VARIEGATED SLATE COMPANY of 419 Market street, Camden, N. J., have been incorporated with a capital of \$200,000, by Geo. S. Matchett, Chas. Burton and M. M. Child. The company will mine Slate.

THE CENTRAL STAMPING COMPANY, after January 1 next, will occupy the entire building at 24 Cliff street, New York City, which is being entirely remodeled to accommodate their business. The company for some years have occupied two floors at 25 Cliff street. Their new offices at 24 Cliff street will be much lighter and more spacious. In the basement they will carry a small stock to accommodate pick-up buyers. The first and second floors will be devoted to sales and sample rooms and the third and fourth floors to counting room and offices.

O'NEIL & GILMER are a new firm who have recently gone into the retail Hardware, Plumbing and Furniture business at Sioux Falls, South Dakota.

During the past fiscal year the State of New Jersey chartered 2342 corporations and received therefrom in fees the sum of \$558,369.54, an increase of \$168,424.67 over the receipts from this source in 1900. This total includes the fees for filing the papers of the United States Steel Corporation, which amounted to \$220,000.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin has advanced 1c. per lb.
Copper prices are unchanged; demand is slow and for small lots.
Pig Lead is quiet and firm.
Spelter is very quiet and without change.
Antimony is unchanged.
Nickel is firm and unchanged.
Aluminum is active at former prices.
Tin Plates are rather quiet; jobbers' prices are softening.
Sheets are still scarce and in sharp demand, with prices strong.
Old Metals are strong, and in good demand.
Sheet Copper is active and firm.
Foundry Iron is very active and strong.
Hardware continues in good seasonable demand, with prices well maintained.
Plumbers' Supplies are moving in good volume, with prices strong in all lines.
Wire Nails are in good demand, but prices show some irregularity due to competition.
Cut Nails are unchanged, and in fair demand.
Wire is active and unchanged.
Window Glass prices are irregular.
Cordage has stiffened.
White Lead is in good demand; prices show some irregularity.
Linseed Oil has been marked down 5c. a gallon.
Spirits Turpentine is in light demand, at unchanged prices.

METAL MARKET.

NEW YORK, November 15, 1901.

Pig Tin.—Up to Wednesday the Pig Tin market remained uninteresting and prices unchanged. On that date, however, a sharp advance occurred, especially on spot and this month's delivery, which was followed by a further rise yesterday, bringing prices up about 1¼c. per lb. from the figures of a week ago. The sudden upward turn is said to be due to an effort to cover certain short interests in deliveries up to the 15th of the month. As stocks on the first of this month were only moderate and arrivals so far have amounted to only 435 tons, with a comparatively small amount due to arrive before December 1, a squeeze on spot was not altogether surprising. Straits Pig in small lots was advanced to 26¼c. to 26¾c. per lb. The market was steady at the close.

Charles S. Trench & Co., New York, publish the following American statistics of Pig Tin:

	Tons.
Estimated stocks on spot, New York, Philadelphia and Boston, October 1.....	1,678
Actual arrivals during October.....	2,555
	4,233
Estimated consumption during October.....	2,800
	1,433
Estimated stocks on spot, New York, Philadelphia and Boston, November 1.....	1,433
Actual afloat from East Indies, shipments to November 1.....	2,245
Actual afloat from England, shipments to November 1.....	145
Actual afloat from Continent, shipments to November 1.....	195
	4,018
Total visible supply, November 1.....	4,018
As against October 1.....	4,891
As against September 1.....	4,476
As against August 1.....	3,478
As against July 1.....	4,068

Copper.—While certain developments of the week had considerable sentimental effect on the market, there was no change as to actual business or prices. Quotations remain unchanged, and consumers continue to buy only according to their immediate requirements. Small lots of Lake Ingot are quoted at 17¼c. to 17½c.

per lb., and Casting Copper at 16¾c. to 17c. Both the United Metals Selling Company, who handle the Amalgamated product, and the American Smelting & Refining Company, have sent out a statement to their shippers notifying them that hereafter they will not settle on shipments of Copper Ore or Matte except upon the expiration of 90 days' time, and upon the prices of that date instead of the date of assay. Similar notices have been posted by other producers, but in following suit they made the time limit 60 days. This move is viewed in the trade as lack of confidence on the part of the producers in present prices. Another important feature of the market was the announcement of the reduction of the price of Copper Wire, from 18¾c. to 17c. This cut was made by the Waelark Copper Wire Company of Elizabethport, N. J., a manufacturing concern established and operated by Senator W. A. Clark, who is president and principal owner of the United Verde Copper Company of Arizona.

Sheet Copper.—There is still an active demand for Sheet Copper from all the consuming interests. Prices are firm, Sheet Copper from store being quoted on the basis of 21c. per lb.

Pig Lead.—The market for Pig Lead is unchanged in any particular. There is a fair business doing, and prices remain firm at the level prevailing for some time past. American Pig in small lots is quoted at 4.62½c. to 4¾c. per lb. St. Louis advices report no new features in that market, with a fair demand and unchanged prices.

Spelter.—The Spelter market here is very quiet. Prices are the same as those ruling a week ago. Good Western brands in small lots are quoted at 4.55c. to 4.60c. per lb. St. Louis advices report a very satisfactory volume of sales, but without any especially large transactions, and prices ruling around the recent level, with firm tendencies.

Sheet Zinc.—The demand for Sheet Zinc is moderate and prices are without change. Jobbers quote 600-lb. cask lots at 6¾c. per lb., and smaller quantities at 7c.

Antimony.—No change has taken place in this metal. Cookson's in small parcels is quoted at 10½c. to 11c., and Hallett's at 8½c. to 9c. per lb.

Nickel.—Is unchanged, prices continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—The demand for Aluminum continues active and prices remain at 37c. per lb. for small lots of No. 1 Ingot, guaranteed 99 per cent. pure, and 35c. for 100-lb. lots.

Tin Plates.—The situation in Tin Plates is unchanged. The market is rather more quiet at present, although there is more or less business doing for deliveries covering the next four months. The American Tin Plate Company are selling only up to the end of the first quarter of this year at present prices. Deliveries from the mills are coming in to the Eastern market rather more freely, and there is a gradual softening of jobbers' prices on all lines of Plates. The small trade are buying freely in a hand to mouth way, the total of such small sales making a fairly large aggregate. Jobbers' prices are still largely nominal, varying according to supply and conditions of sale. American Bessemer Coke Plates, IC, 14 x 20, at New York or corresponding points, rule at about \$5.75 to \$6.25 per box. A further decline of 3 pence in the price of Welsh Plates was noted this week.

Sheets.—The demand for Sheets shows little or no abatement. During the past week or two the run has been heavier on Black Sheets, whereas the demand for Galvanized Sheets was before greater. There is still considerable difficulty in getting prompt delivery from the mills on certain sizes of Sheets, and jobbers find it

hard to fill all the requirements of their customers promptly. Everything in this line that comes into the market is pretty promptly taken up, and stocks in second hands do not yet begin to show any expansion. As an item of interest, and reflecting the present stringency in Sheets, we may note that a large consumer in the Pittsburgh district recently imported quite a tonnage of Sheets from Belgium. The Sheets were not quite as nice looking as the domestic product, but as far as toughness is concerned were just as good and met the requirements of the consumer. Jobbers' prices show no indication of weakening. No. 27 One Pass Cold Rolled Soft Steel Sheets are still quoted in this market at about 4.15c. for small lots and 4.05c. to 4.10c. for larger quantities, where such can be readily supplied. Galvanized Sheets rule at 65 per cent. to 67½ per cent. off the list.

Chicago advices are as follows: Mill shipments are large, yet the scarcity of months ago is not wholly relieved. However, the situation is more comfortable. While some quotations of No. 27 Common are 3.50c., store trade is quite commonly 3.60c. to 3.80c. for that size. Galvanized trade is good, with prices steady at 65 and 10 to 70.

Old Metals.—A good demand is noted for Scrap Iron, and also for some other lines of Old Metals, notably Scrap Brass and Copper. Prices are rather irregular, but they are, as a rule, quite strong. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb.	14¾c.
Light and Tinned Copper.....	per lb.	12¾c.
Heavy Brass.....	per lb.	9¾c.
Light Brass.....	per lb.	7¾c.
Lead.....	per lb.	4 c.
Tea Lead.....	per lb.	3½c.
Zinc.....	per lb.	2¾c.
No. 1 Pewter.....	per lb.	17½c.
No. 2 Pewter.....	per lb.	8½c.
Tin Plate Scrap, per gross ton.....		\$6.50 to \$7.00
Wrought Iron Scrap, per gross ton.....		10.50 to 11.00
Heavy Cast Scrap, per gross ton.....		10.25 to 10.50
Stove Plate Scrap, per gross ton.....		7.25 to 7.50
Burnt Iron, per gross ton.....		5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—Trade is quite as active as furnace companies care to have it under existing circumstances. The demand is heaviest for grades which are in short supply and on which makers have their product under contract far into the future. The leading companies report their sales still running in excess of their current output. We quote: No. 1, \$16 to \$17.50; No. 2 X, \$15.15 to \$15.75; No. 2 Plain, \$14.65 to \$15; Tennessee and Alabama brands, No. 1 Foundry, \$15.50 to \$15.75; No. 2 Foundry, \$14.75 to \$15; No. 1 Soft, \$15.50 to \$15.75; No. 2 Soft, \$14.75 to \$15; No. 3 Foundry, \$13.75 to \$14; No. 4 Foundry, \$13.50 to \$13.75.

CHICAGO.—There has been a good active week in sales of Pig Iron, the aggregate being at least from 15,000 to 20,000 tons. Half of the business was in lots running from 500 to 1000 tons, the buyers providing for their wants during the first half of 1902. The trade has been stimulated by the persistence of reports that Southern Irons were on the point of advancing, the activity being more marked in the Southern products. Some furnaces have raised prices 25c., but there has been no general advance. Foundrymen frequently have trouble in getting old orders filled, and there is a good demand for all the product of the furnaces that arrive, any temporary surplus being quickly absorbed. Local Irons are firm at unchanged prices, as follows:

Lake Superior Charcoal.....		\$17.00 to \$18.00
Local Coke Foundry, No. 1.....		15.25 to 16.00
Local Coke Foundry, No. 2.....		14.75 to 15.25
Local Coke Foundry, No. 3.....		14.25 to 14.75
Local Scotch, No. 1.....		15.25 to 16.00
Ohlo Strong Softeners, No. 1.....		17.00 to 17.50
Southern Silvery, according to Silicon.		15.65 to 16.00
Southern Coke, No. 1.....		15.15 to 15.40
Southern Coke, No. 2.....		14.40 to 14.65
Southern Coke, No. 3.....		13.90 to 14.15
Southern Coke, No. 1 Soft.....		15.15 to 15.40
Southern Coke, No. 2 Soft.....		14.40 to 14.65

PHILADELPHIA.—The demand for Pig Iron is active. Sellers have everything their own way, and it is surprising how little disposed they are to take advantage of

the present condition. Prices are very firm, probably 25c. higher for this year's shipment. A great many large buyers are making contracts for the first three or six months of 1902 at the old figure. In some grades of Iron notable advances have been made, a difference of \$2 to \$3 a ton being noticeable between this week's sales and those made during the early summer months. Foundry Irons, however, have not scored any such material gain, 75c. or possibly \$1 per ton being the limit. No. 2 X Foundry may be picked up at about \$15.25 occasionally, but \$15.50 is a more general price, some quoting \$15.75 firm. Fair prices for Philadelphia and nearby deliveries and about 25c. less for deliveries within a radius of 100 miles south or west would be: No. 1 X Foundry, \$15.75 to \$16; No. 2 X Foundry, \$15.25 to \$15.75, and No. 2 Plain, \$14.75 to \$15.

PITTSBURGH.—We note a heavy demand for Foundry iron, which is scarce for prompt delivery. Several leading manufacturers of Foundry Iron have bought heavily for delivery clear through next year on the basis of about \$15.25, Pittsburgh, for No. 2. The scarcity of Coke caused by the car shortage is still interfering with operations and some of the Valley furnaces have been banked. We quote No. 1 Foundry Iron at \$15.75 to \$16 and No. 2 Foundry at \$15.25 to \$15.50 Pittsburgh.

CINCINNATI.—While the aggregate of Pig Iron orders for the past week may hardly be as large as for the weeks preceding, yet there has been a very satisfactory trade and the favorable conditions have been fully continued. Large orders have been scarcer, but in numbers they have shown perhaps an increase. The business is remarkably well distributed, both as to class of buyers and as to territory. A large portion of the buying is for the second quarter of next year, and for any sooner delivery there is a decided scarcity of many grades. This is especially so in regard to No. 4 Foundry, which is pretty well cleaned up, and on that account is at a premium over the rest of the price-list. There is a very heavy complaint on account of the lack of cars, and both in Pig Iron and Coke circles the grievance is severe. The outlook is for a good steady market for some time yet. We quote, f.o.b. Cincinnati:

Southern Coke, No. 1.....	to	\$14.25
Southern Coke, No. 2.....	to	13.75
Southern Coke, No. 3.....	to	13.25
Southern Coke, No. 4.....	\$12.75 to	13.00
Southern Coke, No. 1 Soft.....	to	14.25
Southern Coke, No. 2 Soft.....	to	13.75
Southern Coke, Gray Forge.....	12.75 to	13.00
Southern Coke, Mottled.....	12.75 to	13.00
Ohlo Silvery, No. 1.....	15.35 to	15.85
Ohlo Silvery, No. 2.....	14.85 to	15.35
Lake Superior Coke, No. 1.....	15.35 to	15.85
Lake Superior Coke, No. 2.....	14.85 to	15.35
Lake Superior Coke, No. 3.....	14.35 to	14.85

ST. LOUIS.—A canvass among the leading interests in the Pig Iron market reveals no change in the conditions which have been ruling of late, orders for 300 and 500 tons being about the maximum for single lots, but the aggregate tonnage of these smaller requirements keeps the order books in a most satisfactory shape. We have advanced our quotations 25c. all through the list, not in the sense of an advance by the furnaces, but as better reflecting the conditions of the market at this center. We quote as follows for cash f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$15.00 to \$15.25
Southern, No. 2 Foundry.....	14.25 to 14.50
Southern, No. 3 Foundry.....	13.75 to 14.00
Southern, No. 4 Foundry.....	13.25 to 13.50
No. 1 Soft.....	14.75 to 15.00
No. 2 Soft.....	14.25 to 14.75

CHICAGO REPORT.

Scrap Iron and Steel.—The demand does not show any great improvement, and prices are shaded to secure business. Dealers quote the following buying prices, in carload lots, Chicago delivery:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast.....	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	... to 8.00
Burnt Iron and Grate Bars.....	5.50 to 6.00
Sheet Iron and Hoops.....	6.00 to 7.00
Plow Steel.....	... to 10.00
Breaking Stock.....	9.00 to 10.00
No. 2, such as Shovels, Hoes, &c.....	... to 7.00
Old Boilers—whole (Iron).....	6.00 to 7.00
Old Boilers (Iron) cut in single Sheets and Rings.....	9.00 to 10.00

Old Gas Pipe and Boiler Tubes.....	10.50 to	11.50
Cast Borings.....	4.50 to	5.00
Turnings	9.50 to	10.00
Horseshoes to	13.00

Old Metals.—A fair business is reported in Metals, principally in Copper and Brass. Prices are higher. Dealers quote buying prices on small lots as follows:

Copper Wire and Heavy.....	Per lb.
Copper Bottoms.....	14 $\frac{3}{4}$ c.
Copper Clips.....	13 $\frac{3}{4}$ c.
Red Brass.....	14 $\frac{3}{4}$ c.
Yellow Brass.....	13 $\frac{3}{4}$ c.
Red Brass Borings.....	9 $\frac{3}{4}$ c.
Yellow Brass Borings.....	11 $\frac{1}{2}$ c.
Light Brass.....	8 $\frac{1}{2}$ c.
Pipe Lead.....	7 $\frac{1}{2}$ c.
Tea Lead.....	4 c.
Zinc.....	3 $\frac{3}{4}$ c.
Tin Foil.....	2.80c.
Pewter, No. 1.....	20 c.
Pewter, No. 2.....	17 c.
	14 c.

Old Rubber.—A fair inquiry is reported, but prices remain unchanged. Dealers' buying prices are as follows:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7 $\frac{3}{4}$ c.
Rubber Car Springs.....	5 $\frac{1}{2}$ c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	7 $\frac{1}{4}$ c.
Black Rubber.....	4 $\frac{1}{4}$ c.
White Rubber.....	8 $\frac{1}{2}$ c.

Rags.—Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at 75c. to 85c. per 100 lbs. in any quantity.

Anthracite Coal.—A heavy demand is reported, and continued complaint is heard on account of the shortage of cars at the mines. The schedule for carload lots is as follows:

	Grate.	Egg and Stove.
Chicago	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

THE HARDWARE TRADE.

The continued strength of the iron market is the most important feature of the present condition and has an obvious bearing on the situation in hardware and related lines. A tone of firmness is thus given to values through the general lines of manufactured products, and especially those in which the raw material is a large part of the cost. Accompanying this firmness in iron and steel is the heavy demand for the cruder products and the good demand for hardware and related lines. At this season orders are for the most part either for, on the one hand, winter and holiday goods and such as are required to complete stocks, or, on the other hand, for next season's delivery, a department of buying which is receiving much attention from the trade. In filling up stocks for winter sale there are many urgent calls upon both manufacturers and jobbers, and in some kinds of goods there is a decided scarcity. Holiday business promises to be of excellent volume, and merchants are preparing to cultivate this class of trade with more enterprise and liberality than usual with a view to making the most of the opportunities which the season presents.

Manufacturers are watching the market closely in view of the condition of the iron market and are careful not to load up with too many orders. There is also more care on their part than usual in regard to terms and conditions, and they are generally taking a more independent position, refusing to guarantee prices, to accept unspecified orders, and in other ways to favor buyers unreasonably. There is little new in the way of reductions or advances. The market as a whole is steady and pretty evenly maintained. Some lines, the prices of which have been recently broken, are getting into a more settled condition on the new basis. The trade generally feel that they are safe in buying according to their requirements, and in lines which are not regarded as under special suspicion on account of indications of weakness or probability of early decline the trade are purchasing with confidence and in good volume.

NOTES ON PRICES.

Plumbers' Supplies.—An excellent demand continues for Plumbers' and Steam Fitters' Supplies in this section. There is an immense amount of both new and repair work being done in New York and vicinity, which calls for a large amount of supplies of all kinds, and jobbers are kept pretty busy meeting the calls of the trade. Prices show no sign of weakening in any direction, and it is not thought that there will be a break in any line of goods this side of 1902. Supplies of such goods as were scarce a short time ago are now more liberal, and the inconvenience and delays lately experienced by reason of the scarcity are now but little felt.

Wrought Iron Pipe.—Supplies of Wrought Iron Pipe in this market are better and, notwithstanding the heavy existing demand, the trade now have little difficulty in procuring all the Pipe needed. Prices continue very firm, with no prospect of a decline for some time to come.

Plumbers' Marble.—A slight advance was made this week in the price of Plumbers' Marble. The demand for this material has been unusually heavy and the Marble men have difficulty in meeting the requirements of the trade.

Wire Nails.—The movement in Wire Nails continues in large volume. While a careful and conservative policy is pursued by buyers in not purchasing beyond their requirements, the current demand is such as to take up readily the output of the mills and the total amount of business is very satisfactory. Owing to pressure of competition prices are not entirely uniform all over the country, although the leading interests are holding theirs firmly. Small lots at store in New York are quoted at \$2.40 to \$2.45 per keg.

Cut Nails.—The market for Cut Nails remains unchanged. There is a very large demand and a better assortment is obtainable as the supply of Steel is better. Small lots from store, New York, are quoted at \$2.18 to \$2.30 per keg.

Wire.—The demand for Plain Wire continues in good volume and the mills are busy, with the likelihood of having steady work through the winter. Prices are unchanged, small lots of Plain Wire being quoted at 2.60 cents and Galvanized at 3 cents.

Window Glass.—Owing to the agreement between the combined domestic Glass manufacturers and the jobbers' association, former quotations are merely nominal, jobbers being permitted to sell at prices which will meet the competition of foreign Glass. The price of Glass from time to time, therefore, will depend on the price at which the outside Glass can be furnished.

White Lead.—Out of town orders for White Lead in Oil are of satisfactory volume, as the fine weather, which has been a feature of the past few weeks, has given an opportunity of finishing up outside work. Some irregularity in price continues. Concessions from regular quotations are reported of $\frac{1}{4}$ to $\frac{1}{2}$ cent, according to brands. Quotations in this market are unchanged at 7 to 7 $\frac{1}{4}$ cents per pound for small lots of White Lead in Oil.

Linseed Oil.—The Linseed Oil market continues in an unsatisfactory condition, there being a wide variation in quotations. On Wednesday the leading producers announced a cut of 5 cents per gallon, due, it was said, to the arrival of Seed. It is asserted by authorities in the trade that this year's crop of Flaxseed will be the largest on record. Raw Oil is quoted at about 60 to 62 cents per gallon for small lots. Boiled Oil is 2 cents advance on Raw.

Spirits Turpentine.—The demand for Turpentine during the week has been light. Large consumers have apparently kept out of the market because they were unwilling to pay current prices. Stocks are said to be amply sufficient for present needs. Retail quotations are 38 to 39 cents per gallon.

THE AMERICAN DISTRIBUTING COMPANY, Syracuse, N. Y., are sending to the trade a four-page circular devoted to their Gasoline and Alcohol Torches. These are

made in a variety of styles for plumbers' use, as well as for gas fitters and painters. The circular gives the list prices as well as illustrations of the line of goods made, and of the various parts that may be needed for repairs. The company also make Brass Ferrules of all sizes, and are prepared to make Brass Castings for their customers.

A New Aluminum Alloy.

Prof. R. C. Carpenter of Cornell University has patented a new aluminum alloy which is claimed to resist expansion, to be hard and of great tensile and compressive strength, while it may be melted at a low temperature and runs with great solidity, making a sharp casting, with relatively small contraction. The ingredients of the alloy are described in the specification as follows: Aluminum, 25 parts; zinc, 25 parts; tin, 25 parts. In preparing the alloy Professor Carpenter states that it is best to first melt the aluminum and then the tin gradually in small pieces and afterward the zinc. The low temperature at which the alloy of aluminum and tin melts permits the addition of the zinc without danger of oxidation or burning. The alloy in the proportions given has a specific gravity of 3.2 to 3.3, a tensile strength of 29,000 pounds per square inch and contracts 8 per cent. in solidifying.

In connection with the subject of the employment of convict labor, it is interesting to note that the books of the Convict Bureau of the State of Alabama show that during the last fiscal year the State secured a profit on convict labor of \$92,832. The convicts in Alabama are hired in the mines, in the saw mills, to the farmers and to the cotton factories, while some are employed on the State farm. The mines pay \$14 per month to convicts, the saw mills \$12, while the farmers pay \$6 a month for the convicts that they employ. It will thus be seen that Alabama manages to make a profit out of her State prisoners, whereas they are a source of heavy expense for maintenance in nearly every other State.

Dr. Hubert Jansen, Berlin (N. W. 7), Dorotheen Strasse, 49, Germany, who is a well-known lexicographer, has been employed as the editor of the "Techno Lexicon," a technical dictionary, in German, English and French, which will be published by the Verein Deutsche Ingenieure. Dr. Jansen is very anxious to receive from American manufacturers copies of their catalogues, price-lists, &c., for the purpose of securing information which he needs in the preparation of this work to enable him to properly set forth the facts required for the English or American department. Quite a number of American firms have already placed their publications at his disposal, but he wishes to secure as full a representation of American industrial matters as possible. The dictionary will be published in three volumes, Vol. I being German-English-French, Vol. II, English-German-French, and Vol. III French-German-English.

A writer in the Gas City, Kan., *Headlight* is authority for the following figures on the amount of work done by a single metal drawer employed in a zinc rolling mill: He makes 95 plates of zinc each shift, or 2950 per month, or 35,200 per year. Each plate averages 62 pounds, making 3790 pounds each shift, or 716,700 pounds per month, or 2,120,400 pounds per year, which would load 70 cars of 30,900 pounds each and make two train loads of 35 cars each. The zinc is shipped of St. Louis and sold at 4 cents a pound, making a total of \$84,816 per year at present prices. These figures are given by a man who is said to have drawn metal for years.

The October fire loss of the United States and Canada, as compiled by the New York *Journal of Commerce*, amounted to \$14,749,000. This is nearly double the aggregate losses of September and more than double the record charged against October of last year. The fire insurance

companies in general are said to have lost a great deal of money this year and an advance in rates is likely to be made. The country's total fire loss for the ten months ending October 31 has reached the sum of \$135,404,000, an average of over \$13,500,000 a month.

**Sheet Metal
Pattern Drafting**

A course of instruction by mail for tinsmiths, coppersmiths, plumbers, sheet-iron workers, furnace workers, skylight makers and others that will enable a student to "strike out" working patterns for all kinds of sheet metal work. This is what a student says:

**His Course
More Than
Paid for Itself**

I am a tinsmith, and consider your course in Sheet Metal Pattern Drafting one of the best investments I ever made. Before I was half through I had realized from it more than the money paid for the whole course.

M. E. TOBIAS, (C)
63 Fifteenth St.,
Wheeling, W. Va.

We teach by mail Mechanical, Steam, Electrical, Civil and Mining Engineering; Shop and Foundry Practice; Mechanical Drawing; Architecture; Plumbing; Sheet Metal Work; Telephony; Telegraphy; Chemistry; Ornamental Design; Lettering; Book-keeping; Stenography; Teaching; English Branches; Locomotive Running; Electrotherapeutics. When writing state subject in which interested.

taught by mail.

TINSMITHS' HELPER and PATTERN BOOK

WITH USEFUL RULES,
DIAGRAMS and TABLES
= By H. K. VosBurgh =
NEW AND IMPROVED EDITION

A USEFUL handbook for tinsmiths and other mechanics, treating simple problems in pattern cutting, such as are of daily occurrence in the shop. An elementary manual for the young tinsmiths. A handy reference for all sheet metal workers.

120 Pages
53 Figures

An Invaluable \$1.00
Pocket Companion . .

**Section 1 ~ Pages 1-66
Diagrams and Patterns**

Demonstrates in a simple way, and by means of illustrations and descriptive text, about 50 examples of sheet metal pattern work, such as the method of cutting can breasts, flared tinware, scale scoops, oval boiler covers, lips for measures, elbow patterns, &c.

**Section 2 ~ Pages 69-88
Epitome of Mensuration**

Compiled with regard to the requirements of the tinner, describing how to find the area of a circle, the circumference of a circle, the contents of a sphere, a cylinder, a cone, and other information relating to the work of a tinsmith.

**Section 3 ~ Pages 89-120
Tables, Rules, Recipes**

Gives tables of the weights of sheet metals, including the weight of black sheet iron, sheet lead, and galvanized iron sheets with their dimensions; the weight of lead pipe per foot; the weights of tin plates, sheet copper and sheet zinc. Several pages are devoted to tables giving the areas and circumferences of circles, the capacity of cans, the number of barrels in cisterns and tanks, sizes of tinware in form of frustum of a cone, &c., and practical receipts, including mixtures for solders of different kinds, soldering fluxes, and various cements.

Galvanizing and Tinning.

A Practical Treatise on Coating with Tin and Zinc, with a Special Chapter on Tinning Gray Iron Castings. By W. T. Flanders. Size 5½ x 8 inches. 93 pages, 40 illustrations. Cloth bound. Price \$2.00.

The author of this work has made a specialty of galvanizing and tinning, and has been employed to erect plants in various parts of the country, also to instruct the owners, so that, in all instances, they have been able to operate them successfully. The subject of galvanizing is, therefore, treated from the standpoint of an expert and in a practical manner. The selection of materials and apparatus for erecting plants of large and small capacity is treated, together with instructions for their equipment and accompanied by many illustrations of the plants and of the tools and appliances. Plain directions are given for the preparatory treatment of metals and articles to be coated, and every detail which is of importance in successfully applying to metals a secure and attractive coating is described. The tinning of articles is treated in the same practical manner. The difficulties found by many who have attempted to tin malleable and gray iron castings are explained and methods for doing the work made simple.

CONTENTS.

Galvanizing.

Locating a Plant and Selecting a Kettle.
The Galvanizing Room.
Tanks for Acids and Other Purposes.
Tools for Galvanizing.
Filling and Firing a New Kettle.
The Use of a Pyrometer.
Materials Used in Galvanizing.
Building and Setting Kettles.
Removing Scale with Sulphuric Acid.
Cleaning Sandy Castings with Sulphuric Acid.
Preparing the Work for Dipping in the Zinc Bath.
Drying the Work.
The Heat of Zinc.
Dipping the Work in the Molten Metal.
The Formation of Dross in the Kettle.
Running Over, or "Sweating," Zinc Dross.

Tinning Malleable Iron, Wrought Iron and Steel.

Preparing the Work.
Tools and Kettles.
A Tinning Plant.
Plan of Tinning Plant.
Removing Scale and Rust with Sulphuric Acid.
Cleaning Sandy Castings by Sulphuric Acid.
Cleaning Sandy Castings with Hydrofluoric Acid.
Removing Paint or Grease.
Tinning with a Single Kettle of Tin.
Tinning with Two or More Kettles of Tin.
Passing the Work Through the Tinning Kettles.
Tinning Wire in Coils.
Tinning Steel Spoons and Similar Articles.
Retinning.
Setting Retinning Kettles.

TINNING COMMON GRAY IRON.

Description of Tinning Plant.
General Considerations.
Tumbling Barrel.
Freeing Gray Iron Castings from Sand by Hydrofluoric Acid.
Cleaning Sandy Castings with Sulphuric Acid.
The Use of a Hot Alkali Bath in Certain Cases.
Preparing the Castings in the Gas Barrel.
Coating the Castings with Tin.

Sent postpaid on receipt of price, \$2.

THE ART OF SELLING.

By F. B. GODDARD.

12mo. Flexible Cloth, 50 Cents.

In this book the author lets the reader into the secrets of the accomplished and successful salesman. Illustrates his tact and finesse, and tells how he masters men; but beyond this, the work embraces much information which will be instructive and useful to all classes of business men. Besides suggestions to buyers, it contains chapters on "Changes in Business Conditions and Methods," "Salesmen's Compensation," "Retail Merchants and Salesmen," "Saleswomen," "How to Read Character," with a collection of clearly and tersely put important Legal Principles and Decisions Governing Sales. Sent, post-paid, upon receipt of price, by

A UNIVERSAL REMEDY FOR LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 800 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails. In 5, 10 and 15 lb. Pails.

Special Discount to Jobbers and Large Buyers.

OLYCON

CONDUCTOR PIPE

WON'T BURST :: The twist in the corrugation checks the sudden fall of ice and water, thus protecting the joints. It stands hard knocks because it is corrugated. Again, it is much handsomer than plain pipe. Made in copper and galvanized iron. Write for catalogue and information, free. Address

Art in Metal Ceilings

"Romanesque Design."

The effort to adapt Classical forms of design and architecture to Christian purposes, resulted in the production of the style known as Romanesque, and, by gradual development it became one of great originality, dignity, and, at the same time, richness in ornamental detail.

Our Romanesque Design of

"Classik"

FACTORIES { Cincinnati, O.
Covington, Ky.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting,
as applied to all branches
of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection of 218 problems and an elaborate explanation of the principles of pattern cutting, including Triangulation.

It embodies the problems of the former Metal Worker Pattern Book, all of which have been revised, and many of which have been entirely rewritten and solved by more approved methods. To these have been added 75 new problems and much other new material and explanatory matter, making this work a model of completeness in every respect.

ARRANGEMENT.

In point of arrangement the new work far surpasses the former one in that the problems are classified under three different heads, and simply indexed, and also that by means of a table of contents any required department of the work can be easily found.

CONTENTS.

While Chapter VI, comprising the greater part of the work, is devoted to the solution of problems, the five preceding chapters thoroughly explain the principles of pattern cutting, and place the student in possession of the preliminary information necessary to a thorough understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials.—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections).—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tanners, Cornice Makers and Sheet Metal Workers should be provided with a copy of

The New Metal Worker Pattern Book.

Price \$5, post or expressage paid.

DAVID WILLIAMS COMPANY,
PUBLISHERS,

232-238 William St., New York.

The Double Truss Cornice Brake.

All the different sizes in which we make this practical machine are herewith illustrated.

This brake costs only half as much as an all-metal brake.

It is made mostly of hard maple.

It is just as good as an iron brake in every respect—much better in some ways. Beside the 50% saved in the first cost our brake will save money in its use.

It is light and can easily be carried from place to place.

By shaping or bending work in the building where it is to be used all the trouble and expense of handling formed-up work is saved.

Near Beekman Street,

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No. 12 gauge, cut wire or bar-steel $\frac{1}{8}$ inch thick, cut off and mitre angle iron $\frac{1}{8}$ inch thick, and do it perfectly.

PRICE, - - \$35.00.

ROUND OAK STANDARD OF AMERICA

CYRTIS GANDY DEL

CHICAGO 1901

Another great feature
in the construction
of the Genuine
Round Oak is

The double fire- pot with anti- clinker grate

and hot blast.
All the draft is
through all the fuel
all the time, giving
perfect combustion
and economizing fuel.
The rim discharge
at bottom of basket
allows all refuse
to pass out and
not clog the fire.
These great features
cannot be had in a
single firepot.
The cone grate holds
the fire to the outside
and prevents the
formation of clinkers.
The hot blast burns
the gases and soot and
makes white smoke—
another reason why
the Genuine
Round Oak is the most
popular heating stove
in this country.
If not sold in your
town write for agency.

Makers Also of

**CRAWFORD
RANGES.**

Finest Factory in this Line in the World.

READ OUR OFFERINGS.

**Special Advantages Over All Other
Heaters.**

OUR HEATERS are only 4 ft 3 in. high, giving excellent elevation for Hot Air Pipes.

OUR HEATERS ARE ALL CAST IRON, no repairing of sheet iron drums necessary every few years.

OUR MANIFOLD TUBES are steel, $\frac{1}{8}$ inch thick, and will wear for a lifetime.

OUR HEATERS are supplied with the most modern grates, perfect dumping and shaking. Each bar can be separately replaced.

OUR HEATERS are so arranged that they can be perfectly cleaned by any one, and in a few moments.

Equally Efficient with Hard or Soft Coal.

Our Heaters save the heat others waste up the chimney and send it through the house, therefore reduce coal bills.

Philadelphia,

Buffalo,

St. Louis,

Minneapolis

and

Denver.

DO you want to sell a good Number One, Medium-Priced Range that will Roast and Bake with the best of them? If you do, then do not be persuaded to carry anything but the...

GEM-MILLER STEEL-PLATE RANGE.

Which are far superior to other so-called first-class Ranges as to Roasting, Baking and Durability that are made.

WITH improved removable Duplex Grate, improved Water Back for heating water, Flue Lined with Pure Asbestos Board, New Non-Warping Oven Bottoms, Cold-Handled Gravity Latch, Drop Oven and Feed Door, Patent Double Centers, Regulating Damper, Nickel-Plated Towel Rod. All bright parts Nickered instead of Polished. Nickel Bands on doors are ventilated to prevent tarnishing, and body of Ranges are highly finished.

Special attention is called to the easy manner of Removing and Replacing the Grates and Grate Frames in these Ranges without interfering with the Water Backs or Linings. Simply by taking out the small bolt and removing the Front Grate the entire Bottom Grate and Frame can be drawn out through the Front Draft Door.

Model Oak

Entirely New Line for 1901.

We use the old name, but the numbers are different.
The Round Air Tight Register is ground into its seat on the inside of the ash pit door and will remain at any degree of opening required to supply air for combustion through the opening.

The register construction is such that the Grate Handle can be pulled out through the register opening.

The Extension on Top of the Fire Pot extends up inside of the steel drum and is cast solid with the fire pot so it cannot twist and warp.

The Sectional Ring fits over the flange turned out on the bottom of the steel drum.

The Ash Pan fits tightly all around the edges of the ash pit.

The joints remain tight.

The price is just right.

Ask for more information.

Nothing Equal to It.

It was Goethe, you recollect, who declared that "to find some one who thinks as I do strengthens my belief." Well, here's what one individual who has thoroughly tested the

GURNEY

"Bright Idea" Heater

thinks of it: "My house is large and exposed, but I can heat the whole of it with the mercury at zero outside. I believe there is nothing equal to the 'Gurney' for heating a house."

If such testimony were rare, of course it would carry less weight, but when we assure you that we have on file hundreds of letters of the same tenor, it seems almost impossible for you not to comprehend the excellence of the "Gurney" Heaters.

But, having comprehended it, why not make use of it? Become our agent and then you'll share its benefits. For just so long as merit finds appreciation, just so long are "Gurney" Heaters bound to sell in increasing numbers.

The Stanton Seamless Heater,

PORTABLE CASED.

STATE COLLEGE, PA., June 15, 1900.

THE STANTON HEATER CO., Martin's Ferry, Ohio.

GENTLEMEN:—The Stanton Heater is giving the best kind of satisfaction. It will produce good heat from any kind of fuel. My average cost of fuel, per month, for the past winter was three tons of coal dust from soft coal to heat 43,000 cubic feet of space with a No. 68 Heater; however, this space is 3,000 cubic feet over the capacity of your Heater, but the heater did the work easy, and held the temperature in zero weather so it would not change over four degrees in twelve hours without touching the Heater.

The Stanton Heater is, in my judgment, the most modern and economical warm-air generator of this age.

Sincerely yours,

J. N. KRUMRINE.

MERCER BOILER,
SQ. FEET WATER RADIATION SUPPLIED 500 TO 5800.

WE haven't told you anything about boilers because we couldn't have filled any more orders up to this time if we had them.

We have just begun to get into a position to fill orders more promptly and solicit new business.

We will sell you a 300, 500 or 800 foot house heating water boiler for a good deal less money than you will pay for any other boiler of anywhere near the same merit.

'Tisn't always what you *make*—it's what you *save*—that counts in year end results.

You can't buy a boiler that is any better in any way, no matter what the price may be.

There are a lot of boilers made that you are asked to pay from \$15 to \$20 more for on a 500 foot size; if you've been doing so, order a sample of us, set it alongside of a high priced one and compare it, either as a whole or piece by piece.

If you are in the business and know anything about what a good heating boiler ought to be, buy something that's really worth the price you pay—real worth as a durable, economical heating boiler—don't pay \$20 extra because of an extensively advertised name on the door.

DIGHTON FURNACE CO., Taunton, Mass.

Front Rank Hot Air Furnaces

are built on vertical lines; air comes in direct contact with entire heating surface.

The Front Rank Fire Chamber is one solid sheet of closely riveted steel; being lined above the fire lines with genuine fire clay tiling it is the most durable made.

The radiators are very large and have an unusual area of heating surface in comparison with the size of fire pot.

These furnaces burn hard or soft coal or coke. We also make wood burning furnaces.

Send for our catalogue, it will give you a better idea of what we make.

AHEAD AS USUAL.

We have not only stood the test of time, but look at the result of physical test of Quimby Engineering Company before Building Committee, on competition for public work in an Eastern city.

QUIMBY ENGINEERING COMPANY.

PHILADELPHIA, PA., Aug. 5, 1901.

MESSRS. J. H. McLain Co., Canton, O.

Gentlemen:—We hereby certify that one-half section of the Cornell Boiler was tested by us to destruction to-day, and that it was ruptured at Two Hundred and Fifty Pounds per square inch hydraulic pressure. Very respectfully yours,

QUIMBY ENGINEERING CO.,

Attest: JOHN M. LUKENS,

H. H. Quimby, Proprietor.
Chief of Bureau of Steam Engine and Boiler Inspection, City of Philadelphia.

It Clearly Puts Our "Cornell" IN A CLASS BY ITSELF.

Think of it—250 pounds pressure on a Cast Iron Boiler. This is the only kind of Boiler that is good enough for you. We make all our Boilers of the different styles the same way—the right way.

Have you our new Booklet, "Truth About Heating?"

THE J. H. McLAIN CO., Canton, Ohio.

"Everything for Heating."

NEW YORK.

CHICAGO.

INDIANAPOLIS.

PHILADELPHIA.

NEW ERA RADIATOR**HOT FACTS**—OF WHICH THIS IS No. 1.

Nature has certain laws. One is that heat rises—another that rapid circulation must be had to heat a room evenly and healthfully.

There are radiators on the market that try to change these laws. But they can't do it. The New Era Radiator conforms to them and extracts the largest amount of heat from a given quantity of fuel. Its principles are right, its construction is scientific and accurate, and it sells at a price that is inducing to every economical housekeeper.

There is money waiting for every dealer who sells the New Era, and we can prove it.

WILMOT CASTLE & CO., ROCHESTER, N.Y.**A NEW AND ENLARGED EDITION.****KITCHEN BOILER CONNECTIONS.**

A SELECTION OF PRACTICAL LETTERS AND ARTICLES RELATING TO WATER BACKS AND RANGE BOILERS.

The attention of readers of THE METAL WORKER is directed to the *fifth and enlarged edition* of Kitchen Boiler Connections, just published. Four editions of this practical book have been sold, giving apparently universal satisfaction, but with a view to presenting a more thorough treatise on the subject, and to enhance the value of the book to the Plumber, Architect and Mechanic, we have incorporated with this edition about sixty-five pages of new matter, together with over forty additional illustrations.

These additions cover many important phases of the subject not discussed in the earlier editions, giving practical solutions of numerous other problems often met with.

The new contents include among other important subjects:

In Chapter I.	Kitchen Boiler Below Range.	In Chapter VIII.	Two Horizontal Boilers Connected with One Water Back.
" VI.	Water Hammer in Boiler Connections.	" IX.	Supplying Hot Water in Large Buildings.
" VIII.	Proper Connection for a Horizontal Boiler.	" X.	Lime Deposit.
" VIII.	Double Water Back Instead of Double Boiler.	" XII.	Hot Water Supply and Heating a Barn.

Examples from actual practice only and which have arisen in the daily work of plumbers and pipe fitters are given in this book, which is therefore practical from beginning to end. Every mechanic, whether expert or novice, should have on hand for constant use or for reference a copy of this the new fifth enlarged edition.

It tells How to Connect Kitchen Boilers and Water Backs Under all Conditions.

It explains Remedies to apply to all kinds of Difficult Cases.

Heating from Kitchen Boilers is fully described.

194 Pages. Size 6 x 9 Inches. 113 Illustrations. Cloth Bound.

Price One Dollar, Postpaid.

DAVID WILLIAMS CO., Publishers, - - 232-238 William St., N. Y.

Books on Heating and Plumbing.

WINCHESTER

How often success in man or goods is ascribed to "luck." We all know better. Intelligence, ability, diligence and merit make for success and not for failure. Do you suppose the "WINCHESTER" steam or water heater would have proved the success it has if it were merely "lucky"? Made by Smith & Thayer Co., Boston, Mass.

HEATER.

After Six O'clock To-night,

OR ANY OTHER NIGHT,

We are prepared to furnish you with hot air wall pipes, not only as good, *but better*, than any other furnace pipe on the market, and to substantiate our claim will mail catalogue and ship sample for comparison, and the *price is right*, too.

Close Buying.

There are many buyers in the lines covered by this paper who are constantly hammering the market and in every way in their power endeavoring to obtain concessions in price from manufacturers and jobbers. This is sometimes done by resorting to practices which are of more than questionable propriety and inconsistent with a high sense of business honor. Those who are charged with the responsibility of buying either the raw material or the finished goods, avoiding this extreme, may at the same time look faithfully after the interests of their important department and maintain their position as close and successful buyers.

There is danger, on the other hand, that this department will be neglected. Many houses, both manufacturers and merchants, apparently do not understand not only the obligation but the necessity of purchasing goods at as low prices as are obtainable, for close buying is a necessary forerunner of profitable selling. This is generally recognized by large concerns, whether merchants or manufacturers—indeed a business is not likely to assume large proportions where this principle is disregarded. The buyer's department in large and enterprising establishments is acknowledged to be one which deserves the best attention and justifies the employment of competent talent. There are, however, many smaller merchants, and even manufacturers, who do not give proper attention to the buying of their goods. They do not appear to consider the money saved by close buying worth the time and trouble necessary to secure low prices, or they are so negligent and easy going in their methods that they do not care to make the requisite effort. Some even labor under the delusion that by paying high prices they win the good will of the manufacturers and jobbers with whom they deal. It is not necessary to point out that this is an entirely mistaken view of the matter, and while they may gain a little in this way, it is at the expense of losing much.

Manufacturers and jobbers do not accord the highest ratings to the houses paying the highest prices. They appreciate dealing with a concern run on strictly business principles, even though its purchases may be limited in quantity. Such a house is generally more favorably considered when favors are desired than the easy going concern paying higher prices. A good business man judges of the house he is dealing with largely by the business qualities shown by it. Close buying is regarded

as a sign of good management which runs all through the business. The lack of close buying is a symptom of poor management which will show itself in other directions. The seller must always watch his credits carefully and be on the alert to detect weakness in those with whom he deals. He is generally willing to extend favors when he can do so with safety, for he desires to hold trade; but, first and last, he is concerned about getting the money due him. This is simply business. Nothing tends more to insure confidence in the good management and stability of a concern than to have goods bought carefully and payments made promptly. Those who are close buyers and avail themselves of the cash discounts are held in higher esteem commercially than houses who are careless in their buying and slow in their payments.

There are many small merchants who are content as a matter of course to pay such prices as are quoted them by the few houses from whom they purchase the great bulk of their goods and without making sufficient effort to ascertain whether or not the prices are as low as could properly be obtained by a little care and attention. While the amount thus lost on each invoice is relatively small, the aggregate during the year makes it a serious diminution from the profits of the business. The trade should recognize the truth of the principle that a saving in this department is as important in a small business as in a large one. This consideration has an added force in view of the fact that buying may be taken as an illustration of the business as a whole. Good buying, good store management, good collections and good profits naturally go together. Where there is careless buying there is generally found careless management in every department.

Foreign Boilers.

At various times we have alluded to the fact that the sale of house heating boilers abroad has increased and that several American houses find it profitable to devote special attention to this class of trade. In order that a more correct idea of the outlook for business in this field may be had by American manufacturers, we begin, in another part of this issue, a three-part article on "European Heating Boilers." The article is profusely illustrated and shows all the various types, from the simplest constructions to those of the highest efficiency. These illustrations will doubtless provide acceptable information to many of our readers, although they may not desire to embody in their productions all the characteristics shown. Nevertheless, it is probable that in some of the constructions useful hints may be found. The text, in connection with the illustrations, gives the heating value placed on different characters of heating surfaces by the Germans, who more than other engineers have carefully tabulated the information gained in testing various types of heating apparatus for both efficiency and economy. These articles, we are sure, will be found of value as a review of foreign boiler construction and for reference and comparison by the manufacturers of heating goods here. From the American point of view, however, it is doubtful if the foreign constructions will be as highly thought of as those which can be secured in this market.

How to Win Foreign Trade.

Methods for securing foreign trade frequently have formed the subject of communications from our consuls in different parts of the world. All these officials agree that American manufacturers and exporters in general too often fail to use practical and common sense methods to accomplish this end. In a recent report to the State Department, United States Consul William A. Prickitt, at Rheims, France, says that he is continually receiving letters from merchants in this country requesting the names of dealers in his consular district, and that he has answered hundreds of such letters, but is sure they have accomplished very little. The inquirers do not realize the obstacles in transacting business with foreign merchants by correspondence. The difference in the money, in the measures of a quantity, and the important matters of duty and freight do not seem to be given the consideration by American merchants and manufacturers that they deserve. The consul asserts that the French merchants will not take the trouble to translate English letters into French, nor make the calculations necessary to turn dollars and cents into French money, or English measures into French, nor will they investigate as to freight and duty charges. The majority of American exporters insist upon quoting goods f.o.b. New York or other ports, instead of calculating and naming the cost the French merchants will have to pay for the goods delivered at their destinations. If the latter course was pursued, the consul is confident that excellent results could be obtained in France. At the same time, he reiterates the advice given by many consular officers and other authorities on foreign trade that the best way is to send competent representatives to the large distributing centers of the country who will solicit trade at first hand. If this course is not possible, the next best method is to engage the services of a reliable local agent who will do business on commission. Selling goods directly by correspondence, and so avoiding commissions, is plausible in theory, but it does not succeed in practice.

The Importance of Technical Education.

In a recent article on the influence of technical education upon the industrial prosperity of a country, Prof. V. C. Alderson referred to the advantages gained by Germany in recent years as a proof of the superiority of the industrial educational system followed in that country. Professor Alderson finds that the system of training in technical colleges and schools is the main source of Germany's industrial power, enabling her within recent years to become one of the great manufacturing nations of the world, and to force her way into foreign markets in competition with the United States and Great Britain. Nevertheless, he is of the opinion that the technical schools in the United States, while not equal to the German schools in point of theoretical training, excel them on the practical side, the American tendency being not only to master knowledge, but to apply it at once. It is this practical efficiency that accounts for the remarkable industrial progress of this country. With the increased facilities for technical training which are constantly being provided there is little doubt this progress will be still further stimulated and accelerated. Not only in the constant improvements which are being made in the production of iron and steel, but in their manipulation as they are transformed into the finer finished products, are illustrations to be found which emphasize the practical utility of

technical training. The American alertness in applying the discoveries of science and in adopting improved methods, which are not always simply labor saving, has much to do with the country's marvelous success in manufacturing.

Furnace Heating.

The Metal Worker has called attention on several occasions to the frequency with which furnace heating is adopted for fine residence buildings, and this fall has been no exception to the past in the number of times to which our attention has been drawn to the superior class of buildings in which hot air furnaces have been installed. In corresponding with us recently, on another subject, a prominent heating engineer stated that he thought the subject of furnace heating to be "a much more important one than heating engineers generally seem to consider it." A letter from another leading engineer includes the statement that "the furnace system of heating has been neglected by heating engineers rather more than its importance would warrant." Such opinions, expressed by engineers who are employed for consultation on the construction of extensive systems of heating and ventilation in which steam is used, are evidence of the esteem in which the furnace system of heating is held by men of broad information. We present these views for the encouragement of furnacemen and as an inspiration for the younger men who are inclined to have a higher regard for steam and hot water heating. They should study the subject of heating broadly, so that they may be qualified to recommend to their customers a hot air, hot water or steam system, whichever may best be adapted to their needs, with a perfect familiarity with all of the advantages of each system.

Agricultural Prosperity.

In spite of the partial failure of the corn crop the farmers, as a class, have enjoyed a remarkably prosperous season. According to the *American Agriculturist*, which is probably the highest authority in such matters, the wheat yield of the United States this year is worth \$150,000,000 more than that of 1900, while the shortage of corn and potatoes has been entirely offset by the higher price obtained for those products, and the crops of barley, oats and rye make up quite as large a total in amount and value this year as last. Moreover, live stock represents a value of nearly \$250,000,000 over last year. The prices of apples and other fruits, too, have risen materially. Consequently the farm products of the United States this year may be reckoned as worth fully \$400,000,000 more than last year, which was accounted a season of fair prosperity. Coming after four good agricultural seasons, it would seem that the farmers have every reason to be grateful and contented in the opening year of the twentieth century. The increase in the value of farm products during the past five years has been little less than stupendous. The value of the cereals—wheat, corn, oats, rye and barley—raised in this country from 1897 to 1901 represents an increase of nearly \$1,000,000,000 over the preceding five years and live stock has appreciated to a similar amount. Cotton growers have received about \$400,000,000 more in the past five years than in the previous five, and the agricultural exports of this country have been greater in value by \$938,000,000 in the same period. The bearing of these facts upon the general prosperity of the country is obvious, and the promise they hold forth of an active winter's business in all lines of trade is gratifying in the extreme.

TRADE WITH MEXICO.

The renewed attention to trade conditions between the United States and the American countries lying south of her borders, due in part to the meeting of the Pan-American Congress in the City of Mexico, lends special interest to a statement made by a British Consul in Mexico, which has just been received by the Treasury Bureau of Statistics. The officer in question calls the attention of his Government to the fact that in the one American country at the south with which the United States has satisfactory transportation facilities—namely, Mexico—the trade of the United States has vastly outgrown that of other nations. Fifty years ago trade with Mexico was carried almost exclusively by British houses, and such was the condition as late as 1872 and 1873, but since the opening of the Mexican Central and the Mexican National railways the United States manufacturers have increased their trade with the Mexican Republic, and the British trade is now confined to a few agencies—there being no important commercial establishment—which, by means of samples and catalogues, undertake the execution of orders. Some of the larger British firms still employ special representatives, but they cannot count on their usual customers for orders. Other houses frequently send out such incapable men that they are unable to get a single order.

The consul calls attention to certain points which he says have been much overlooked by the British traders, and it would not be inadvisable for American manufacturers to take note of the hints suggested. He says that there are over 900 different classifications in the Mexican tariff, and lists of articles that clearly specify those on which a duty exists are issued by the Minister of Finance. These can be obtained on application. More care should be taken in drawing up invoices, so that the many mistakes now found may not occur. These mistakes lead to the imposition of fines and consequent loss to the consignee.

The consul also refers to the subject of packing, to which more attention should be paid. This does not refer particularly to the outside case, but to the way in which the contents are packed in the case. Merchants or customers abroad often give instructions as to the packing of certain articles, not only to secure their safe arrival, but also on account of the duties that may be leviable on these goods. If these instructions were properly carried out a great deal of trouble on both sides would be saved.

Delay in the execution of orders is also another serious drawback to the extension of trade. Such delays, he says, several times have been the cause of important orders being sent to the United States or some European country where they can be filled at once. Another point deserving attention is the failure to give estimates or descriptions when asked for, and in this connection the absolute necessity of giving the would-be customer an intelligible description of the goods, together with the metric weights and measures, is insisted upon.

In connection with the trade of the United States with Mexico it is of interest to learn that in the last decade, from 1891 to 1901, the value of exports from this country to the republic has grown from \$14,900,000 to \$37,500,000. The rapid rate at which this trade is increasing is also illustrated by the fact that in two years it has increased in amount more than \$11,000,000. The United Kingdom, the next largest exporter to Mexico, now sends only about \$10,000,000 worth of goods to that country.

At Pittsburgh, in the case of the Pittsburgh Supply Company against the Pittsburgh Meter Company, the Circuit Court found in favor of the plaintiff. This finding was reversed by the United States Circuit Court of Appeals, and the bill of the complainant was dismissed.

Over \$7,080,000 in gold bars, the largest withdrawal from the Assay Office in one day on record, and the largest shipment to be consigned to one transatlantic steamship, left New York on Tuesday on board the "Kaiser Wilhelm der Grosse" for Europe.

THE EASTERN STOVE TRADE.

The feeling existing in the stove trade in the East is different from that which prevails in many other lines. For some time past a strong tendency has been manifest toward combinations and associations. This method of improving trade conditions and eliminating bad practices, which are sure to creep into any trade, is quite generally in favor. The manufacturers of Eastern Pennsylvania, New York City and the upper Hudson, after deriving benefit from association and frequent meetings at the Astor House, have discontinued these conferences; at least so far. No call has been issued for a meeting for some time, and while no statement has been made that the old organization ceases to exist, there is no evidence of its life. Eastern Pennsylvania, however, which has always been tenacious of the association idea, after disrupting through the flagrant violation of its rules the old association, has again reorganized on a new plan, with a paid secretary.

THE PAID SECRETARY AND THE RULES.

The workings of this association have been watched by those who are members and those who are not, with considerable interest. In operation the association have agreed upon certain rules for the classification of goods and the fixing of list prices on all new goods by a special committee. After agreeing on list prices for various goods they have also fixed the discounts which make the selling price, no restriction, however, being put upon those who desire to secure higher prices for their manufactures. Naturally these who are not members of the association, as well as some who are, desire to market their products at concessions from these prices. A part of the work of the association has been for the secretary to learn where outside manufacturers have made concessions and then to allow the members to meet them.

THE EXCEPTIONS SUPERSEDE THE RULE.

One of the larger houses belonging to the association is authority for the statement that the major portion of the sales are made at prices in accordance with the concessions reported. To have an official of the association report where concessions may be made is an advance over the old somewhat demoralizing custom of having every salesman on the road hunt out these concessions and report them. It is probable that the new method has a somewhat less demoralizing effect, besides the advantage of putting all who are allied in their interests on practically the same level by furnishing a record of the concessions that may be made. Close observers of the general results are of the opinion that during the season when other manufacturers of cast iron goods were securing good profits, the stove manufacturers in Eastern Pennsylvania, New York City and the upper Hudson have failed to secure as profitable prices for their goods.

VIOLATION, OPEN MARKET AND REDUCED PROFITS.

The charge is made that some manufacturers high up in association affairs have no hesitation in making special prices or in placing on the market attractive new goods without consulting the Price Committee as to what list prices they shall use, but independently adopting a list price of their own making, sometimes lower than, or similar to, the regulation list. Thus, at the same discounts their more elaborately equipped goods are sold at figures that increase their attractions. In consequence there has been what may be generally termed an open market, which has been by no means a disadvantage to the buyer of stoves. It is possible that the dealers are influenced more or less by the low price they have secured from the manufacturers and have retailed their stock with a smaller margin of profit than is good for their bank account or the new 60-day payment rule of the National Association.

TENDENCY TO INDEPENDENT ACTION.

The natural outgrowth of this condition is generally toward independence of action by individual plants, untrammelled by restrictions that may be more beneficial to competitors than an independent course would be to a house that is willing to enter into a contest for the survival of the fittest. Much has been said in favor of

associations and many benefits may be derived from them. Nevertheless, it is evident that a stove manufacturing business, conducted with a high order of intelligence that will utilize all progressive methods in the course of production and exercise vigilant care in the details of its administration, can be successful and derive the special benefits which attend individual enterprise, and without being a menace to the best interests of the trade as a whole.

VIOLETIONS DESTROY ASSOCIATIONS.

There are many elements and factors in the stove trade in the territory under consideration which seem to be irreconcilable. If a continuation of the association is desirable it will be necessary for a stricter adherence to agreements than heretofore has been customary. In all bodies there are those who fail to see how their interests can be served by adherence to the rules and their violation is always a source of annoyance. There is still another class who are shrewder and take advantage of the rules for their personal gain in a most exasperating manner. These offenders are quite generally noted for their suavity in ignoring any restrictions on their actions, rather than for their loyalty to either the spirit or the letter of their agreement. These are the conditions which may be said to have killed the interest in many once beneficial associations. They are also said to be responsible for the hesitancy on the part of those who favor the association to make any endeavor to renew life in the old association or to form a new one.

A LEADER OR A GOVERNING BOARD?

Many are of the opinion that a strong man is necessary to take the lead in the work of reorganization. This would heap an immense deal of work and responsibility on one man, and from the fact that such a leader is not forthcoming, it is probable that the idea is entertained that such a demand is unreasonable. If the association fails for the lack of such a man measures might be taken for the operation of an association under a board of governors cognizant of the sharp practices of the various members, who would be more powerful in treating with offenders than a single officer could be. It is possible that such a board of governors, utilizing the Pennsylvania idea of a paid secretary, could bring order out of the chaos into which the Eastern stove trade seems to have passed. In connection with such a movement there would probably be little difficulty in securing an official thoroughly familiar with every detail of the stove business, and also with the practices of the various manufacturers who engage in it in the territory which he is employed to cover. A fund of official information could in this manner be brought to the attention of the Board of Governors, and it would then rest with the whole association to carry out the measures recommended by them.

HEATING IN EUROPE.

BY AN AMERICAN ENGINEER.

The first impression an American engineer receives of European methods of heating, be it with stoves, warm air furnaces, steam or hot water, is that they are far behind those used in the United States. This is due to the fact that they use clumsy and unsightly stoves, crude registers and rough radiators, while in the piping there is a lack of that neat fitting which one is accustomed to see in America. They bend their pipes, using very few fittings, and where these do come into use they are clumsy flanged devices. In the smaller sizes of pipe, say under 2 inch, they use wrought iron fittings, which are seldom standard in size.

But a closer study discloses the fact that the Europeans generally, and the German engineers particularly, are far ahead of the American in many ways. For instance, they figure more exactly; their apparatus is built in every case for the particular work expected of it, the kind of fuel and the attention it is to receive. Hence their apparatus is more economical in the use of fuel, it needs less attention and admits of the most precise regulation, a result seldom obtained in the United States, where economy in use is not sought so much as small first cost, in consequence of the hustling

competition that may well be termed "that insanity to get a contract."

The European engineer is more concerned about his reputation and results than about his profits, for the European property owner does not forget, as does the American, that he was deceived, nor can an engineer whose work defaults hope to continue in business as he can in America, where, according to Barnum, a "sneaker is born every minute."

Every system of warm air furnace heating has in connection a system of ventilation. Hence a given number of changes of air per hour are easily secured. The warm air flues are invariably constructed of tile or brick and with the shortest horizontal travel. The warm air is introduced in all cases more than head high, and the police and insurance regulations are so strict that a warm air furnace heating apparatus is as safe and healthful and costs as much as a low pressure steam heating apparatus.

For steam or hot water heating apparatus the regulating and safety appliances used are nearer the point of perfection in Germany than anywhere else in the world. The open stand pipe used on steam boilers makes an explosion practically impossible.

The European engineer is far ahead of the American in making tests and records of results in all kinds of work, and when he makes a test he promptly gives it to the profession generally through the trade papers.

The fact that almost every German engineer speaks English and French, or at least is able to read those languages, enables him to keep in touch with what is going on in the world outside of Germany. Being very adept at copying, the German engineers are not slow to profit by any advance made in America, England or France, and with the experiments and tests made in their own thorough, painstaking way, they manage easily to keep ahead of the balance of the world.

New Model Grand Range.

One of the latest novelties which have been added to their already extensive assortment of specialties by the Barstow Stove Company of Providence, R. I., is the

New Model Grand Range.

Model Grand range, a general view of which is presented herewith. As will be seen, the exterior is ornamented in a most effective manner, the name plate forming a conspicuous feature of the treatment of the oven door. Constructively the range embodies the latest improvements. The main top is entirely devoted to cooking space, this being brought about by an ingenious arrangement of the smoke flue. The oven is fitted with a rack, which can be pulled out to its full width. By means of a simple locking device it remains rigidly in position, thus affording opportunity for readily handling baking pans, &c., without the necessity of reaching into the hot oven. The rack can then be pushed back into position, while at the same time it is as readily removable as the ordinary rack. It is plated with aluminum, so that it can be easily cleaned. Another feature of the new Model Grand is

the ash pan, which catches and holds all the ashes in the fire box. By means of the automatic lift dust guards the pan is removable nearly on a level, thus differing from the ordinary pan, which has to be lifted out at an angle of 45 degrees. The handle is so placed above the surface of the ashes that it can be readily reached when the pan is full. Still another point to which the company draw attention is the nickel trimmings of the range, all of which are detachable for the purpose of cleaning or repairs.

ODD PLATES.

THE president of the Auer Register Company, Toledo, Ohio, is making a business trip through the East in the interest of their special construction of Side Wall Registers. These Registers are especially adapted for use in vertical heating flues and can be adjusted so that all of the heat can be thrown into the first floor room, or a portion of the ascending hot air current can pass to the upper Registers.

THE daily press of New England reports that Richard E. Warner of the Stove manufacturing concern of White-Warner Company, Taunton, Mass., has been nominated for Mayor by the Republicans of that city.

CHARLES C. HEATH & Co., Baltimore and Philadelphia, will greatly extend their Philadelphia store, which, under the management of Henry Swartz, has been very successful. It is reported that a large new warehouse now being erected in the Second Street District will be taken by them and stocked with a full line of Stoves, Heaters and Ranges.

A PRETTY FOLDER which is being sent out by the Michigan Stove Company calls attention to the Art-Garland Parlor Heater, which they are offering in three sizes plain and one size with oven. The Stove is of handsome appearance, nickel being liberally employed in its ornamentation, and has the company's reflector top. The Stove is surmounted by an ornament of artistic design finished in gold. Other attractive features include large hot air circulating flues, extra heavy grate and fire pot, double swing cover, shaking and duplex grate, and patent screw draft register in the ash pit door. The Art-Garland is designed for burning hard coal or crushed coke, and every Stove is a double heater. The company are constantly in receipt of very complimentary letters relating to their goods. In their mail recently was a letter from a customer in Loda, Ill., in which he refers in very high terms to the excellence and satisfaction of the Garland goods, and to the pleasure derived in handling the company's line of Stoves and Ranges.

A LITTLE FOLDER which is being sent out by the Symonds Mfg. Company of East St. Louis, Ill., calls attention to what is known as the Symonds Register, which may be readily opened with the foot. Directions are given to the tinner and carpenter for installing the Registers, and tables are presented showing prices, weights and dimensions. The manufacturers claim for the Register that it protects the wall from discoloration, deflects the air further into the room, is easy to operate even in the dark, requires no special pipe or box patterns, is readily kept clean, necessitates no cutting of the carpets, is graceful in design and unsurpassed as a foot warmer.

THE management of the Estate of P. D. Bockwith of Dowagiac, Mich., are constantly in receipt of letters from customers testifying in the most flattering terms to the merits of the Round Oak Stoves, Ranges and Heaters. In their mail not long ago the manufacturers found a letter from a customer in Elkhart, Ill., to the effect that he had been in the Stove business for 35 years and had handled a number of good Ranges, but stated that the Round Oak Steel Range was the most perfect one he had ever seen, and since handling it his trade had steadily increased. He laid special stress upon the workmanship, weight and handsome appearance of the Range as attracting much attention, and, being carefully fitted and constructed, gives surprising results in the way of baking with a comparatively small amount of fuel.

THE PORTLAND STOVE FOUNDRY COMPANY of Portland, Maine, are offering the trade what is known as the Im-

perial Atlantic Oak, an attractive Parlor Heater, intended for using wood or coal as a fuel. The construction is such as to render it easily managed, and the claim is made that it will keep a fire continuously and economically. It is made with return flue, has brick lined fire pot and is referred to as powerful in operation.

THE GATE CITY STOVE WORKS is the name of a concern who have just been incorporated, at Catlettsburg, Ohio, for the purpose of placing upon the market a new Gas Stove known as the Wilson. The incorporators are Messrs. McCloskey, Wilson and Kinner, who for some time past have held the patents on the Stove, and who have now rented the Kirsh Building on Main street for the purpose of carrying on the new business. We understand that the Foster Stove Company of Ironton are to make the different parts of the Stove, which will be assembled by the new concern at their factory and made ready for the market.

THE JAMES SMART MFG. COMPANY, LIMITED, Brockville, Ontario, Canada, manufacturers of Perfection Stoves and Ranges and high class heating goods, are sending to their friends a nicely finished brass edged foot rule. The name and address of the company are inscribed on one side and on the other is printed a recommendation of the Kelsey Generators, for which the concern are the Canadian agents.

THE STRICKLER STOVE COMPANY is the name of a concern recently incorporated at Keokuk, Iowa, with a capital stock of \$24,000. The incorporators include Henry and A. S. Strickler, H. W. Huiskamp and A. E. Matless.

THE WASHINGTON FOUNDRY COMPANY, who were incorporated last summer at Spokane, Wash., with a capital of \$5000, are busily engaged meeting the demands of a growing business. While the force of hands at present employed is comparatively small, when considered in the light of other Stove plants, the management are progressive and pushing and feel that, in course of time, they will build up a large trade.

THE PENINSULA STOVE COMPANY, Detroit, Mich., have been sending out to customers a display card entitled "The Family Tree of Greatest Oak, and the Cause of Its Growth." The picture represents an oak tree of immense size growing in a forest, the giant roots extending in many directions and partially concealing a Stove plant of large proportions. Resting upon the limbs of the tree are several varieties of Oak Stoves, including the Peninsular Double Heater and Hot Blast, the Oak Peninsular Hot Blast Smoke Consumer, and two styles of a low priced Oak Heater.

THE FRONT RANK STEEL FURNACE COMPANY of 2301 to 2309 Lucas avenue, St. Louis, Mo., have issued a very neat 28-page pamphlet illustrating and describing the leading specialties which they manufacture in the way of heating apparatus. The prime object of the little work is to present in a simple and comprehensive way the subject of heating the home with a Warm Air Furnace. The merits of the Front Rank, which is made in several styles and varieties, are set forth in a way to interest the dealer as well as the house owner. Numerous tables show the sizes in which the heaters are made and give dimensions of various parts. One of the tables is devoted to a price-list of Registers finished in black or white japan. An interesting feature is a series of half-tone reproductions from photographs of residences heated by means of Front Rank Furnaces.

AYLING BROS., manufacturers of the A. B. Stove Polish, with main office and works at 8 to 14 Haddon avenue, Chicago, are meeting with good success. They say that this season's sales are the largest since they commenced business in 1881. The firm have opened a branch office in Milwaukee, Wis., at 486 Mitchell street, in charge of R. J. Koch, where they carry a stock, making deliveries direct from that branch.

THE HENRY N. CLARK COMPANY, Boston, Mass., are sending to the trade circulars of a timely character relating to heating apparatus. One shows a Kerosene Oil Heater, which has a cast iron base supporting a brass oil font, and having a burner with a 10-inch wick. The

upper part is made of planished iron, perforated, and is furnished with a handle for carrying. The Fire King, presented in another circular, is a box Stove made to burn wood, from 18 to 36 inches long. The Pearl is an oval wood air tight, having a cast iron top and bottom and made to burn wood from 13 to 23 inches long. A six-page folder is devoted to a special oval all sheet iron Air Tight Stove and the Rival Oak Stove.

THE ADAMS COMPANY, Dubuque, Iowa, are distributing Catalogue No. 7, devoted especially to their Hardware Specialty line. It illustrates Diamond Extension Flue Backs and Front Grates, Diamond Adjustable Cook Stove Damper, Diamond Stove Pipe Damper, Diamond Vise, Adams Register, Barrel Truck, Gradometer, &c. They have recently added several new articles to their line.

THE J. D. SMITH FOUNDRY SUPPLY COMPANY, proprietors of the Cleveland Facing Mills, are erecting a large addition to their extensive plant at Cleveland, Ohio. Warehouse capacity for machinery and supplies has been increased by leasing the five-story building at 36, 38 and 40 South Water Street, in same city.

THE S. OBERMAYER COMPANY of Cincinnati and Chicago, dealers in Foundry Supplies, will open a branch house in Pittsburgh, where they will carry in stock a full line of equipment for iron, steel and brass foundries. A building has been secured, 40 x 100 feet, with yard room of the same size, and the building will be extended to 80 x 100 feet. William Fitzpatrick, already well known to the Pittsburgh trade, and A. Rosenberg, from the Cincinnati plant, will have charge of the Pittsburgh house.

The Improved Star Nail Puller.

The Atwater Mfg. Company, Plantsville, Conn., are putting on the market the improved Star nail puller, shown in the accompanying illustration. The feature of the new puller is the small amount of travel at the top, which on a puller measuring 19½ inches high is less than 2 inches, which does not leave the arm bent so as to interfere with a strong pull. The puller is of truss construction, self opening, no springs being used, and, it is stated, is always ready for use. There are no slots or bolts in the foot to wear or become loose, it consisting of two cheek pieces, one riveted on each side of the jaw and a foot which operates on the outside of the jaw having a downward motion, which, the manufacturers state, tends to push the jaw under the nail head instead of lifting. On the inside of the foot the part working on the jaw has a concave face which fits into the convex outside of the jaw, locking the foot and jaw and preventing any side motion. The construction of the truss makes a convenient place for the hand out of the way of the ram, and also gives a firm grip to prevent

The Improved Star Nail Puller.

twisting on the nail. The pullers are made in two sizes, large and small, oil tempered, finely finished, and wrapped in oiled paper.

INCORPORATION papers have been taken out for a Paint company, known as the Orr, Dean & Barry Company, successors to the Orr & Abbott Paint Company, Columbus, Ohio. The officers of the new company are as follows: President, Oliver Orr, Columbus; vice-president, Geo. M. Gray, Coshocton, Ohio; secretary, Geo. Barry, Columbus; treasurer, H. Clay Dean, Columbus; superintendent, B. B. Naylor, Columbus. Mr. Orr was one of the original owners of the Orr & Abbott Paint Company, who were established in Columbus in 1879. Messrs. Dean and Barry have been traveling salesmen for the Orr, Brown, Price Drug Company of Columbus,

the former for the past 13 years, and the latter for the past 11 years. Mr. Naylor is a practical Paint maker, and has a wide experience. Geo. M. Gray is engaged in the retail and wholesale Hardware business in Coshocton. The company will continue to manufacture the high grade Liquid Paint that has been on the market for a number of years. Everything is now being made ready for the active prosecution of business, and salesmen will start out on the road within the next few weeks.

The Ocean Wave Washing Machine.

Voss Bros. Mfg. Company, Davenport, Iowa, are offering the washing machine shown herewith. It is made on the rotary, reciprocating plan, the reciprocating

The Ocean Wave Washing Machine.

ing motion being imparted by a tilting rack. The rack is engaged by a pinion on the fly wheel shaft. As the fly wheel and pinion are revolved the rack is tilted in a position to alternately allow the pinion to travel on the top and bottom sides of the rack, to impart a reciprocating motion to the interior working parts of the machine. The manufacturers remark that all friction is practically eliminated by having no sliding motion to the driving mechanism, also that the machine is practically noiseless. The machine is constructed of heavy Mississippi cypress throughout, corrugated sides and bottom, with three heavy flat iron hoops, well painted and varnished, heavy hinges, convenient fastening, &c. The fly wheel is fastened to the shaft by means of a hook or key, which can be readily removed and the wheel taken off, which will make the machine lighter to carry, also relieving

the hinges and cover of its weight when opening the cover. It is explained that the wood work being finished with the best paints and varnishes, the iron work with japan, and the fly wheel in wine color, the machine is attractive in appearance.

CHICAGO SOLAR LIGHT COMPANY, Department 32, Chicago, Ill., issue a catalogue of the Nulite Incandescent Vapor Gas Lamps, which are referred to as burning about 94 per cent. of air and 6 per cent. of hydrocarbon gas, making a pure, steady, strong and economical light. The catalogue illustrates the line of these Lamps which the company are making, including Wall, Table and Student Lamps, two, three and four light Chandeliers, Indoor and Outdoor Arc Illuminators, Street Lamps, &c.

The Knight in the Window.

The knight in the show window of Morley Bros., Saginaw, Mich., has attracted much attention and favorable comment. His feet and body were constructed in the tin shop of the store from IC roofing tin, the arms being formed of galvanized conductor elbows. The shield was cut from the cover of a dripping pan. To form the head and neck respectively a 3-quart tin milk kettle was used, and in this was put a No. 5 football players' helmet with a gauze face. The sword was made of a No. 1 drill rod with a No. 8 hog scraper for handle. The entire figure was covered with one coat of

The Knight in the Window.

aluminum and gold bronze paint. This window exhibit was prepared by F. L. Kalde, a retail salesman in the store.

Stove and Hardware Dealers.

ALTHOUGH he has had a vacation for 44 months, as he puts it, J. Sydney Smith is well remembered by the Stove and House Furnishing Goods trades of the New England States, among which he traveled for many years as representative of one of the leading Stamped Ware houses. Mr. Smith dropped in at the Boston office of *The Metal Worker* to say that he has recently made a little trip of one week around the circuit to renew old acquaintances, and incidentally to seek additional outlet for the product of the manufacturing establishment of which he is now the president and general manager. Mr. Smith's old friends in the trade will be glad to know that he has made a success of the J. Sydney Smith Mfg. Company of Weymouth, Mass., by running it on a strictly moral plan. The entire force of his factory, we are informed, avoid the use of tobacco and intoxicating liquors, and regularly attend church on Sunday. Mr. Smith makes it a point to keep in close touch with every employee, and is able to vouch for their conduct, both as workmen and members of the community. The output of his factory consists of Hand Forged Solid Punches and Chisels for tinsmiths and Plumbers' Calking Irons, and, we are advised, the factory is now running to its full capacity.

RUMAGE, MALONE & COOPER is the style of a new concern who have lately opened up in the Hardware, Stove, Tinware, Agricultural Implement and Sporting Goods lines at Hobart, Oklahoma. They will carry on a wholesale as well as retail business.

J. MANGAN & SONS, retailers of Shelf and Heavy Hardware, Stoves and Tinware, Agricultural Implements, Sporting Goods, &c., Beresford, S. D., have incor-

porated under the style of the Mangan Hardware Company, and on January 1 next will assume and continue the business. They purpose enlarging their facilities so that they may be in a better position to look after the requirements of their patrons.

CULLER BROS. have lately opened up in business at Perrysville, Ohio, handling a stock comprising General Hardware, Stoves and Furnaces, Farm Implements, Paints, Varnishes, &c.

GRAY & BENNETT have opened up a new retail business at Flandreau, S. D. They will carry a full line of Builders' Hardware, Stoves, Tinware, House Furnishing Goods, &c. They will also conduct a department devoted to hot air, steam and hot water heating and ventilation.

ROLLMAN Mfg. COMPANY, Mount Joy, Pa., are sending out a postal folder, calling attention to their Rollman Apple Cutter and Rollman Cherry Seeder.

ACCORDING to advices from Pittsburgh, some of the leading manufacturers of Lamps have set on foot a movement for a consolidation of the Lamp factories of the country, with a capital of about \$10,000,000. This is the second attempt to form a combination in that trade. It is understood that the promoters will endeavor to avoid the obstacles which prevented the successful consummation of the scheme in the past. Interests identified with the Pittsburgh Lamp & Brass Company are said to be prominent in the present negotiations and five or six leading concerns are reported to have signified their willingness to join the proposed combination. It is expected that the organization, if successful, will not be definitely accomplished until some time next year, although the promoters are now actively working to perfect their plans.

THE partnership of Rennie & Johnson, trading under the firm name of the Linwood Stove & Tin Company, Marcus Hook, Pa., has been dissolved by mutual consent. The firm were composed of John W. Rennie and Benjamin Johnson, Jr.

J. J. CRONAN & Co. are making a special push for a share of the Stove and Range business of New Haven, Conn., by a fine stock and display at 6 Church street. They also do plumbing, steam and hot water heating, and have a well equipped tin shop.

THOMAS K. NIEDRINGHAUS of the National Enameling & Stamping Company's St. Louis branch was a visitor in New York City this week.

THE WHITTAKER-WEBER TINWARE MFG. COMPANY, North St. Louis, Mo., are about to increase their capitalization from \$100,000 to \$250,000. Early in the new year they will occupy a new \$125,000 addition to their present quarters at Second and Talcott streets. The company have enjoyed a surprising growth in the Tinware and Galvanized Iron and Steel Ware lines.

THE LEONARD REFRIGERATOR COMPANY, Grand Rapids, Mich., are building a large addition to their establishment corner of Market and Fulton streets. The new building will be connected with the present plant by bridges, and the two buildings combined will form one of the largest Refrigerator establishments in the country.

"Compressed Air" and "Mechanical Movements" are the titles of two new books which have recently made their appearance, written by Gardner D. Hiscox, an engineer of well-known ability. "Compressed Air" is described as a complete treatise, and it will be interesting to many who desire to use compressed air for lifting water, operating pneumatic tools, for cleaning castings and for other purposes. "Mechanical Movements" will be found a valuable book of reference in many shops where machines must be devised for various purposes. The task will be materially simplified by referring to the many different characters of mechanical movements and motive powers adapted for special requirements, as explained and illustrated in this work.

In Germany new houses are being supplied with floors made of compressed paper. They are soft to step on, and having no cracks of any kind harbor no dust.

European Heating Boilers.

BY CHARLES F. HAUSS.

IN THREE PARTS. PART FIRST.

Steam and hot water heating is more of a science in Europe than in America. Though America excels in foundry and machine shop practice, she fails to give

boiler is built for a particular purpose, fuel and condition. For instance, a boiler built for low pressure or open tank hot water heating is never used for middle or light pressure hot water heating, or *vice versa*. And the same rule applies in steam heating. To use the words of one of the pioneers in the boiler business in America, "They never prescribe a remedy without a reason." Each type of boiler is made in many sizes, with the grate and fire

the many details that help to make up a heating apparatus the earnest thought and time that the slow going but thorough German devotes to it. It is to the German that the other engineers of Europe look for their suggestions and ideas. Hence many parts of heating apparatus made in England and other European countries were inspired by the Germans.

Though, at first glance, the following illustrations may not impress the reader favorably, the writer is sure that a close study will convince the reader that each

surfaces accurately figured. Hence it is not necessary at any time to use a boiler that is much larger than is wanted.

One class of hot water heating that is receiving a great deal of attention just now, and that is being extensively installed, is that of heating a flat or small house from a boiler built into the kitchen range, as shown in Figs. 1 to 7. Fig. 1 shows the Meyer boiler, made up of cast iron sections, connected at the top and bottom with wrought iron slip nipples, which are made

in eight sizes, with from 22½ to 56 square feet of fire surface in two sizes of section, and rated to supply 2600 heat units per square foot of fire surface, which is equivalent to 14 square feet of two-column direct radiation per square foot of fire surface, and containing an average of 2 pounds of water per square foot of fire surface. In this boiler, which has the grates cast on the sections, the fire passes upward, striking the range top, then downward on each side through the side flues into the sub-base, which acts as the entrance to the chimney flue.

Fig. 2 shows the Warns, Gaye & Block Telescope

boiler has a fixed grate and is intended for use in combination with the cooking range, as shown in Fig. 3. The smaller fire pot on the right is intended for use in summer or when it is desired to use the bake ovens. Fig. 5 shows this same range with steel casing.

In Fig. 6 is shown the red metal water back used for heating water for domestic purposes in the summer. The claim made for it is that, being composed mostly of copper, it will not fill up with scale as rapidly as would a cast iron water back.

Fig. 7 represents the Liebau boiler, having an adjustable grate, which can be set at three different heights,

EUROPEAN HEATING BOILERS.

boiler, bricked up in a tile range, Fig. 3 presenting a sectional view and Fig. 4 the boiler itself. It is made in 13 sizes, ranging from 17 x 17 x 20 inches to 30 x 30 x 33 inches outside dimensions, with from 11 to 59½ square feet of fire surface, rated to supply, for the inside or direct surface, 4500 heat units, and for the outside or flue surface 2600 heat units, per square foot of fire surface, equal to 24 and 14 square feet of radiation and containing about 2 pounds of water per square foot of fire surface. The metal, which is 5-16 inch thick, is wrought iron, welded or brazed together, so there are no rivets used in its construction, yet it withstands the hydraulic pressure of 90 pounds per square inch demanded by the German Government. This particular

thus requiring but one fire pot for summer or winter use. It has practically the same proportions as the boiler shown in Figs. 2 to 6.

The Victoria boiler, which is the simplest type of straight fire pot boiler, is presented in Figs. 8 and 9. It is made in ten sizes, with from 3 to 12 square feet of fire surface. Being what is termed "contact" surface, in that it comes in direct contact with the fire, it is rated to supply 7200 heat units per square foot of fire surface under best conditions, which means 36 square feet of direct cast iron two-column radiation per square foot of fire surface. Figs. 10 and 11 show this same boiler with a magazine.

Figs. 12 and 13 illustrate the cylinder boiler, which is

of the same general type, except that the fire pot gets smaller nearer the top and the water space increases correspondingly.

In Figs. 14 and 15 is given what is the best known and most used type of round fire pot boiler, the dome or dome top boiler, made in 18 sizes, with from 4 to 31½ square feet of fire surface and rated to carry from 144 to 1134 square feet of radiation. It ranges from 13 to 30 inches outside diameter and from 21 to 60 inches in height, is made of 5-16 and ¾ wrought iron (welded), and is provided with a deep fire pot and magazine feed door; also with screw draft openings similar to those used on the American oak stoves.

Figs. 16 and 17 represent a trunk boiler, a plain rectangular box, with top feed and direct draft, designed for heating greenhouses, made in nine sizes, all 21 inches high and from 18 x 18 to 24 x 47 inches wide and long, and having from 8 to 21 square feet of fire surface, rated to supply 33 square feet of radiation, or 6000 heat units, per square foot of fire surface per hour. Figs. 18 and 19 show the same type of boiler with a return flue,

with quarter moon diving flue, is illustrated by Figs. 26, 27 and 28. It is made in ten sizes, with 16 to 62 square feet of fire surface and rated to carry 448 to 1750 square feet of radiation, based on each square foot of fire surface supplying 5000 heat units per hour. This boiler contains about 3¼ pounds of water per square foot of surface.

Figs. 29 and 30 show the Planet boiler with and without magazine, which, except for the arrangement of the sliding feed door, is practically similar to Figs. 8 to 13.

Figs. 31 and 32 represent the Derby boiler, which is flat in front and round behind, with the magazine door and smoke flue side by side, so that the flue plate inside forms a sort of a return flue boiler. It is made in 24 sizes, with from 3 to 23 square feet of fire surface, rated to supply from 100 to 760 square feet of direct radia-

EUROPEAN HEATING BOILERS.

but designed for larger work, and made in 11 sizes, with from 22 to 45 square feet of fire surface, the direct or fire pot surface being rated to supply 6700 heat units and the back flue surface 3700 heat units per square foot of surface.

Figs. 20 and 21 show the Windsor boiler, with top return flue, which is rated the same as Fig. 18 and is made in 14 sizes, having from 11 to 38 square feet of fire surface, rated to supply 6000 heat units for fire box surface and 3700 heat units for the return flue surface per square foot of fire surface. They have an average of 1½ square feet of grate surface and about 2½ pounds of water per square foot of fire surface.

In Figs. 22 and 23 is shown the improved Severn boiler, of oval form, with top return flue and a large down draft flue at the back, in which are staggered water tubes, increasing the fire surface. It is made in 13 sizes, having from 25 to 170 square feet of fire surface, which is rated to supply, on an average, 5000 heat units per square foot of fire surface. This same Severn boiler in round form is shown in Figs 24 and 25 without the diving flue.

The Sichel boiler, a round boiler of rather odd design,

tion, based on each square foot of fire surface supplying 6000 heat units per hour.

All the boilers delineated in Figs. 8 to 32 are portable boilers, made of wrought iron 5-16 to ¾ inch thick and welded or brazed together, and are intended for use as tank heaters or for heating flats, greenhouses, &c.

In Figs. 36 and 37 the Zenith or Climax boiler is given, with top magazine feed and quite a tortuous route for the products of combustion to travel from the fire to the chimney flue. It is made in 16 sizes, with 19 to 145 square feet of fire surface, rated to carry 425 to 3520 square feet of direct radiation, based on the fire box surface supplying 6500 heat units, flue 3900 heat units and the outside surface 1800 heat units per square foot of fire surface per hour.

Figs. 38 and 39 represent the common Saddle boiler and Fig. 40 the method of setting the same in brick. These boilers are made in 20 sizes, with from 12 to 49 square feet of fire surface, rated to carry from 280 to 1100 square feet of radiation, based on the inner surface supplying 6000 heat units and the outer surface 2600 heat units per square foot per hour.

Figs. 41 and 42 show the Windsor boiler and its

method of setting. It is made in 29 sizes, having 22 to 134 square feet of fire surface, of which the fire box surface gives 6500, the return flue surface 3600 and the outside surface 1800 heat units per square foot of fire surface. The ratio of grate to fire surface ranges from 1 to 20 up to 1 to 30, and the boiler contains about 4 pounds of water per square foot of surface.

In Figs. 43 and 44 the Telescope boiler and its setting are presented. This boiler is designed for larger systems of heating, principally for residences, where the large central magazine insures an even temperature with the minimum of attention. It is made in 18 sizes, with from 15 to 148 square feet of fire surface, rated to carry 364 to 3700 square feet of direct radiation, based on the inside surface supplying 6500 heat units and the outer surface 2600 heat units per square foot per hour.

Fig. 45 is the Chatworth boiler, Fig. 46 the Cross-Saddle boiler, Fig. 47 the Beacon boiler and Fig. 48 the Kaiserin boiler, while Figs. 49, 50, 51, 52, 53 and 54 show different types of Saddle boilers, with or without magazine feed, back or side flues, and rated and proportioned the same as those shown in Figs. 38 to 42.

(To be continued.)

BRITISH HEATING AND VENTILATING ENGINEERS.

The autumn meeting of the British Institute of Heating and Ventilating Engineers was held at the Holborn Restaurant, in London, on October 22, with some 50 members in attendance, and President W. R. McGuire of Dublin in the chair. A paper was read by C. Mason on "Low Pressure Hot Water Heating with Special Reference to Dwelling Houses," and one by F. Milan on "Domestic Hot Water Supply, and Explosions in Kitchen Boilers." In the first paper is the statement that the cost of a plant for heating most houses thoroughly in the hall and principal rooms will be about the return for a year's rental, and this can be taken as a guide in estimating this class of work in England. In the discussion of the paper the president favored a system working satisfactorily with the temperature of the water from 160 to 180 degrees, and for determining radiation he believed in the rule of 200, 20 and 2, which requires the cubic contents of the room to be divided by 200, the wall area in square feet by 20, and the glass area in square feet by 2, the products to be added together to determine the square feet of radiation needed. This, however, was without allowance for a change of air, and when the room was satisfactorily ventilated the figure derived by dividing the contents by 200 should again be added.

From the character of the papers and the discussions it appears that this society is doing an important educational work in the heating and ventilating trades.

The Subject of Trap Ventilation.

Since the "higher criticism" by some Eastern lights has touched the ventilation of plumbing systems, which had been considered as unquestionably "the correct thing" by the trade, there has been some agitation of this once settled question by the laymen, principally from a financial point of view. In this connection some interest may be taken in the following account from the *Times* of Beverly, Mass., on a recent meeting of the Council of that city, when the plumbing ordinances were taken up for consideration:

Councilman McDonnell offered an amendment to Section 9, so that "all buildings having more than one water closet" be furnished with a vent pipe run from the crown to the trap.

Councilman Hamilton did not favor the change, for it would work a hardship on the poor workingman who is trying to build for himself a home.

Councilman McDonnell: "I would like to ask how many of the so-called poor people have more than one water closet? Some houses at the Farms have 14 or 15 water closets, and I maintain that it is absolutely necessary to have vent pipes."

Councilman Hamilton said that he knew of several buildings which have more than one water closet.

Councilman Boyden said that this provision was in the favor of the poor man. This clause will protect the poor

man from the owner of tenement blocks, for it insures good plumbing. "I have been told that the additional cost would not be over 10 per cent. on the total cost."

Councilman Fröst was called to the chair and President Pierce took the floor.

Councilman Pierce could not see the necessity for the amendment. Back vents are unnecessary in many cases; then there is an element of danger in these back vents by lodgment in aperture. "I do not think back venting is necessary. We have had no epidemics arising from unsanitary conditions, and 90 per cent. of the traps in this city are not back vented."

He asked if any members of the Council had their traps back vented, and Councilman McDonnell, a plumber, was the only member who could remember of having his trap vented.

"We will excuse you," said Councilman Pierce, and the Councilmen laughed at the joke.

Councilman Hamilton: "The Board of Health should be and is qualified to judge what is necessary to protect the health of this city, and if they favor the section as in this ordinance then I am prepared to vote for it."

Councilman Pierce showed a drawing on back venting and then the amendment was put. It was defeated by vote of 13 to 3.

HOW WE LEARN.

BY THE STUDENT.

One morning during a rather protracted cold spell, about three years ago, I found the following letter in our mail:

" ————:

"The water heating system you placed in my house has been a tremendous comfort to us so far this winter, both day and night. Until recently I have taken much pleasure in showing it to my friends and neighbors, and have taken care to mention your name in connection with it on such occasions. As a heating arrangement I am more than satisfied with it.

"I am, however, greatly surprised at its having developed astonishing qualities as an ice producing plant as well. Now you said nothing in your proposal about providing such a paradoxical attribute. Did you wish to surprise me by giving extra value for the stipulated price? If so, I am sure you cannot correctly gauge your generosity until you come and look at the glacier enveloping the extension of my house. I wish I could appreciate your thoughtfulness, but I can't. My friends living near persist in calling here, under pretext of making terms for ice for the coming summer, and you see that this is trying.

"Seriously, I don't want any ice—much prefer getting it in the usual way, from the ice waggon. Can't you send a good man out in the morning who can suspend this inconsistent operation of our heating system? I'll wait until 10 o'clock for him. I must ask this of you, as the architect, who lives opposite, says the weight may be disastrous. Yours faithfully,

For a few moments after reading this I must confess I was twisted. However, I sent a man out, and the case developed this way: We had used an automatic expansion tank on the job, and had run the overflow through the side of the house, just under the eave, and 2 feet above the tinued flat roof of a 10 x 14 extension. Every time the fire became low the water in the tank fell, and, as a matter of course, filled up again by means of the city pressure. Each time the fire was "mended" the tank overflowed, and, the weather being extremely cold, the water froze on the roof as fast as it escaped, until the ice had built up to the end of the overflow and extended in great icicles beyond the edges of the roof.

There was no other place to run the overflow to; we would gladly have run it to the cellar, but the owner's wife objected strenuously to showing more pipe through the house. We finally removed the automatic and replaced it with a good sized galvanized tank, using the same overflow, with an automatic air valve on it to prevent siphoning. We haven't heard a word about ice since.

The moral of this is not that we condemn the use of automatic expansion tanks (we use them yet), but to simply throw out the hint that when planning the overflow from one just "think it over."

Master Plumbers' Interstate Convention at Norfolk, Va.

Members of the Master Plumbers' Association of Baltimore, Md., are planning a lively jaunt for themselves and their wives on the occasion of the interstate convention, to be held at Norfolk, Va., on December 9. At their regular meeting on November 14 they elected the following delegates and alternates to attend the convention: President Lloyd Mitchell, State Vice-President P. T. Berry, John Trainor, W. H. Rothrock, August Eidman, W. H. Henkel, E. Zimmish, R. H. Whitney, William Kelly, William Dulaney and Thomas Hibberts; alternates, M. Miller, H. Rossbach, William Mitchell, A. Zimmers and William Eckard. The delegates and many others will leave Baltimore on Saturday, December 7, and will stop off at Old Point for Sunday, where they will meet the delegates from Delaware, the District of Columbia and other parts of the State. This is the first interstate convention ever held, embracing Maryland, Delaware, Virginia and the District of Columbia. The convention will meet in Emerald Hall and will hold its sessions for two days. The Norfolk plumbers have prepared an attractive programme for the entertainment of the visitors.

Plumbing Regulations in Porto Rico.

Evidently the authorities in Porto Rico are pursuing a commendable course in reference to the plumbing regulations, as will be seen by the following extract from the *San Juan News*:

The plumbing regulations recently issued by the Superior Board of Health regarding the registration of plumbers, plumbing, &c., has caused considerable unfavorable comment among those engaged in the trade.

This matter has been discussed at meetings of the various labor unions. President Timothée of the Federación Regional sent a letter to the Superior Board of Health, questioning the legality of the regulations and claiming that the action is detrimental to the working class.

Dr. W. Fawcett Smith has considered the facts as presented by Mr. Timothée, and yesterday answered his communication, calling his attention to several important points in the regulations which will benefit both the people and the plumbers.

It is the intention of the Board to at first issue a license to artisans and at the end of about a year, which is sufficient time to gain a fair knowledge of plumbing, to give those holding licenses an opportunity to pass a higher examination for a certificate.

Inspection of plumbing work, and the examinations, will be conducted by those who have no direct or indirect connection with the local trade.

As to the legality of the regulations, Doctor Smith stated that the Attorney-General had been consulted, and upon his approval the regulations were issued.

Needed a Steam Fitter.

From the Middle West a story has just blown in, says the *Paper Trade Journal*, concerning a well-known paper manufacturer who is so genial and jolly that he tells it on himself. Some time ago he began to feel badly. Then he felt worse, and finally he reached that stage where, in reading patent medicine ads, he imagined he had all the symptoms described in all of them. The next step was to go to a doctor, who advised him to go to Hot Springs for a month.

The patient followed the advice. When he arrived at the Springs, one evening, the hotels were so crowded that as a mere temporary arrangement he was given an 8 x 10 room, being promised better accommodations next day. He went to bed, but the heat was so intense that he could not sleep. The air was stifling, and perspiration rolled from all his pores, until, by the aid of a lively imagination, he worked himself into such a state of mind that he believed that he was nearing the point where it would be necessary to indicate what disposition his heirs should make of his belongings. At this point he sent for a physician, to whom he told his long tale of woe, laying particular stress on the fact that he was in a very desperate condition, one of the symptoms being that he was drenched in perspiration.

The doctor listened and then said: "You don't need a doctor; you need a steam fitter to turn off the steam to that radiator at the head of your bed." It is recorded that he recovered.

Introducing Solvents Into Boilers.

Various methods have been adopted for introducing dissolved solvents into a steam boiler for removing or preventing the formation of scale. This is sometimes done through a pump and again by means of an injector. These different methods ordinarily work very well in practice, but we have occasionally had complaints, says the *Locomotive*, to the effect that the soda ash, when passed through the pump, eats out the packing thereof. We think this would hardly be likely to occur with a new packing, but with an old one, which had become impregnated with oil or grease, the soda ash might easily give some such trouble as has been reported.

To assist those who have difficulties of this sort, we present herewith another plan for introducing the dissolved solvent, by means of which it is forced into the boiler without passing through the pump at all. The present arrangement calls for more piping than the ones previously shown, and its only advantage is that it saves the pump.

Referring to the illustration, A is a section of big pipe—say 6 inches in diameter and 30 inches long, which

Introducing Solvents into Boilers.

is to serve as a reservoir. This connects with the feed pipe running from the pump to the boiler, by means of the pipes B, C and F, which are so arranged that they connect with the feed pipe on opposite sides of the stop valve D. Over the reservoir is a funnel, K, by means of which the reservoir A can be filled through the valve H. The reservoir A is provided with pet cocks, a and b, at the top and bottom, so that it may be readily filled and emptied. A union is provided at C to facilitate the assembling of the piping. (A right and left elbow, of course, may be used instead, if it is preferred.)

The device is used as follows: The reservoir A being empty valves E and F and pet cock b are first closed, and valve H and pet cock a are opened. The soda ash solution is then poured into K, until the reservoir A is filled. The valve H and the pet cock a are then closed, as well as the valve D in the main pipe. Valves E and F are then opened and the pump is started. The device is then in the condition shown in the engraving and the water from the pump passes around through B, C and A, as shown by the arrows, sweeping the contents of A out into the boiler.

When the pump has been run long enough to thoroughly remove all soda ash from A, valve D may be opened and valves E and F closed. The reservoir A is then emptied by opening pet cock b, and either pet cock a or valve H, and the device is again ready for operation.

Bagging Live Gas Mains.

At the twenty-ninth annual meeting of the American Gas Light Association, held in Boston in October, the following paper, under the above title, was presented by P. H. Gibbons of Philadelphia:

A complete and successful shut off depends more on the proper placing of the bag than upon the lung power of the person who inflates it. Upon the rapidity of the operation quite frequently depends the operator's capacity for labor during the balance of the day. If he makes three or four unsuccessful efforts to bag a main against strong pressure his companions either pull him out of the trench, or he staggers out himself, weak kneed and sick. A violent, throbbing headache is his portion for the balance of the day, which makes it physically impossible for the poor fellow to render you little more than 50 per cent. of his labor efficiency. It has ever been to me, and perhaps to all of you, a deplorable sight to see workmen overcome with gas on crowded thoroughfares, where a gaping throug is sure to quickly gather; and they are never slow in expressing their sentiments of adverse criticism touching the "carelessness of the foreman, the neglect of the company and the villainess of the stuff they are selling for gas." I have given the subject of bagging live gas mains some thought, and while I have accomplished little in the right direction, that little will perhaps attract the attention of brighter minds, with the result that this portion of main laying will be made pleasanter and safer for the workmen, and less expensive for the company. The mains most difficult to completely shut off are those that are filled with dry scales and naphthalene and rust. A rubber bag that is soft and pliable makes the best stopper for a main of this character, and it should be so placed as to get an even pressure at all points of contact. Old mains are frequently found to be very rough on the inside and have little baracles of dried up tar (some of which are porous), which add to the difficulty of bagging off. A rubber bag makes the best stopper for a main of this character. The rubber bag does not make a safe or reliable stopper for a main that is imperfectly drained, especially if the liquid contains oily matter. The oil dissolves the rubber and bursts the bag. A stopper or a canvas bag works better in a main of this character. After the main is cut and the deposit drained off a rubber bag can then be safely placed in the same hole with the stopper or the canvas bag; we have an established rule here to place two bags in each open end, so that if an accident happens to one bag the other will take care of the gas. To rapidly and accurately place bags in live mains so that when inflated the axis of the sphere and main coincide, I have designed the "City District Bag Fork." When the bag is thrust through the bag hole the prongs of the fork can be readily slipped over the bag stem, close up to the pole of the bag, a distance a little greater than one-half the diameter of the pipe, or just enough to allow for the angle formed by the bag with the bag hole. The bag is then carried forward into position, and a luting of clay placed over the bag hole prevents further escape of gas while the bag is being inflated. I have used the fork daily on intersection work since August 26. During that time I had to deal with mains from 2 inches to 30 inches, and have not had a man to complain of headache caused by escaping gas. I find that any of my laborers can readily place a bag accurately with the fork. The fork is made of wire, which gives the prongs greater flexibility than could be obtained from solid material. It is simple of construction and offers no square or sharp edges to injure the bag. The fork described in this paper is made to readily pass through a 1-inch brass "bag saving device," and will handle rubber bags from 3 inches to 12 inches. The stems of canvas bags being larger and more cumbersome than those on rubber bags, they require a fork with wider space between the prongs. On intersection work we frequently find it both convenient and economical to drill one bag hole in the center of the cross, causing that bag to shut off all the gas coming from three directions; but, if necessary to use more than one bag, the fork enables us to place a separate bag at each branch, while we are cutting and removing the iron and lead from the other. I always use a rubber bag for this purpose, one size larger than the cross to be bagged off, and put it straight down, holding the pole of the bag well up against the bag hole while it is being inflated. In this way I invariably make a complete shut off. There is extreme danger, however, of puncturing the bag while cutting the old spigot out of the bell, unless the bag is protected in some way. To shield the bag and give added security against accidents I have designed the "City District Bag Shield," which consists of a piece of steel spring wire, shaped to snugly fit the main, a piece of oiled canvas being drawn over the ring. The ends of the wire are bent outward so that they can be grasped with the thumb and forefinger; when it is desired to put it in position the ends are pressed toward and overlap-

ping each other, which reduces the size of the ring and permits it to enter the pipe. By putting a light luting of soap around the edge, the shield not only protects the bag but the workman as well, since it will prevent all escape of gas that might pass the bag. In bagging the arm of a 6, 8, 12, 24 or 30 inch cross or tee I prefer to drill the bag hole close up to the bag and use a rubber bag a size larger than the arm, holding the pole of the bag well up to the bag hole while inflating it. I then secure it by means of a piece of twine tied to the bag stem.

New York City Notes.

Trade still continues brisk. Byrne & Murphy are doing the plumbing in a large factory building on Twentieth street, west of Eleventh avenue, for the Nassau Smelting Works, and in a loft building at Sixteenth street and Seventh avenue. C. Hensle has apartments on 113th street, near Lenox avenue; J. J. Fleming an eight-story apartment at Manhattan avenue and 111th street, Smith & Roffen an apartment on 109th street, near Amsterdam avenue, and J. W. Cooney a residence at 19 West Fifty-fifth street and a ten-story apartment at Sixty-third street and Madison avenue for the Fuller Construction Company. Jackson & Griffin are at work on a tenement at 211 East Broadway, John Frick has an apartment at 221 West 107th street and J. C. Wexted a tenement at 48-50 James street.

* * *

The trouble between the Amalgamated and Brotherhood societies of journeymen has caused an almost total suspension of work on the Ansonia Hotel, where M. Schnaier & Co. are the plumbers. The plumbers are working steadily, but enough trades or parts of trades have been called out in sympathy to about stop the interior work.

* * *

The Manhattan Branch representatives to the Greater New York Association, after one or two bad defeats, have completely turned the tables in bowling, and are now the recognized champions. It is said that new representatives to the Executive Committee next year will be chosen principally for their bowling capabilities.

* * *

John McAdam of 2353 Broadway has shown that he possesses what some of the alleged comic papers have denied that plumbers have—a conscience. Having been recently converted and joining the Lexington Avenue Baptist Church, he felt that the one thing lacking was a parsonage. So he presented the house 129 East 111th street to the church for that purpose.

New Swedish Acetylene Generator.

United States Consul Robert S. S. Bergh, at Gothenburg, Sweden, reports that Erik Cornelius, chemist at the carbide factory at Trollhättan, Sweden, has invented a new acetylene gas generator, called the Trollhättan, which is described as follows:

This generator is said to be much simpler in construction than former ones, and occupies little space. The falling of the carbide into the water is automatically regulated by a rubber ball, which, as soon as it is filled with gas, closes the valve between the carbide and the water. When the volume of gas decreases the hollow rubber ball contracts and the feed valve again permits the carbide to drop. The gas is stored partly in the rubber ball and partly in the space between the funnel shaped carbide magazine and the water. If much gas is generated the water is pressed through valves into the water jacket in the sides of the apparatus, thus furnishing more room for the gas. A separate gas tank is therefore not needed. Should too much gas be produced, water and gas escape through a safety valve. Common carbide is used; no cartridges. The gas is dried by being allowed to pass through the carbide magazine, where the carbide absorbs the moisture. As there is no gas tank, and the quantity of gas stored thus is insignificant, it is considered that the fire insurance companies will, without raising the insurance premiums, approve of the apparatus, even when it is placed in dwelling houses.

Changes in the Central Foundry Company.

The Central Foundry Company, 116 Nassau street, New York, have notified the local trade that hereafter their Monitor store at 76-80 Centre street, New York, will remain open for business on Saturday afternoons until 4 o'clock. Heretofore the Monitor store was closed on Saturdays at noon. On November 1 the Central Foundry Company replaced C. B. Bird, who had been with the old Monitor Iron Works for the past nine years, and who had succeeded Mr. Decker as manager of the Monitor store, by J. Wiggins. Mr. Wiggins was formerly bookkeeper and manager for Leonard D. Horsford of Beekman street, New York. Prior to that time he was employed in the capacity of traveling salesman by the M. Reynolds Plumbers' Supply Company and the Henry McShane Mfg. Company in the New York branch. We also learn that Alfred Fowler, who was formerly general manager of the Central Foundry Company and who left that concern to take a position as manager of all the branches of the Crane Company, has returned to the Central Foundry Company to resume his old position as general manager. George F. Ross, who has held the position in the interim, is to be placed in charge of a new department of the Central Foundry Company. He will have entire charge of the coal mines and the manufacture of pig iron. This change in the forces of the Central Foundry Company was brought about by the ill health of Mr. Ross, he being unable to stand the climate of this vicinity. The policy of the company will remain unchanged.

To Eat His Hat.

A special of November 16 to the New York Times from Louisville, Ky., contained the following in reference to one of the most popular men in the plumbing trade. Those who know him have no doubt that he will discharge his obligation with his usual good humor, and in such a way as to further extend the friendships he so widely enjoys:

Thomas P. Watts, sanitary plumber, is in for a rare treat and must eat his last season's straw hat. He is game and says he will do it. A hot political debate resulted in the following agreement:

"September 25, 1901.—I, Thomas Watts, am at present wearing a straw hat, which I propose to eat if the Republican ticket is not elected this fall.

"THOMAS P. WATTS.

"Witnesses—GEORGE W. HINSLER, HERMAN V. COHEN."

Mr. Hinsler is proprietor of the English kitchen and Mr. Cohen is advertising manager of the *Anzeiger*. The Republican ticket was unsuccessful and Mr. Watts is being held to his wager. A banquet is being arranged at the English kitchen next week, for which Mr. Watts must pay, and the menu will be as follows:

Soup.
Old straw.
Entrees.
Fricassee of straw.
Ragout of straw.
Straw hash.
Salad.
Straw, with pitchfork dressing.
Dessert.
Straw pudding, with old braid sauce.
Sulphuretted water.

Mr. Watts is game and says he will eat the hat.

Cutting and Threading to Sketch, Free.

The Ideal Mfg. Company, Detroit, Mich., have instituted a new scheme to enable them to sell their products in greater volume than heretofore. The officers of the company have decided to cut and fit, free of charge, nickel plated tubing to sketch for all kinds of special work wherein the products of this company are installed. In a letter just issued the company say:

The great demand for the Ideal volumeters, low tank combinations, centrifugal traps, fine thread tools and fittings, has demonstrated to the officers of the Ideal Mfg. Company that the plumber appreciates the manufacturer who invests his capital in the interests of the trade, and, with this encouragement, increased facilities have been added to our plant, making it the largest factory in the

world manufacturing high grade plumbing specialties, and in such form as to enable the plumber, by use of adjustable traps and nickel plated fittings, to install all kinds of special work at a great reduction in cost. We cut and fit nickel plated tubing to sketch for all kinds of special work, for railings, vent and waste pipes, free, no charge for labor.

The P. and S. S. League.

President Haff of the Plumbing and Steam Supply League had the pleasure of seeing his team, the F. N. Du Bois & Co. bowlers, win two games at the Monarch Alleys in New York on Monday night. All the men on the F. Ade & Co. team were out again, but were unable to avoid two defeats, while the Central Foundry Company team won and lost.

On Thursday night a surprise came in two victories for the team of John A. Murray, breaking their line of continuous defeats, while the team of E. F. Keating lost two games and kept their line of defeats still unbroken. The Salesmen won and lost a game. Henry Stein made a good score—better than Good's good score of 210—by making 222, the highest individual score yet made. G. W. Tilton of the John A. Murray team made 189, and F. J. McCarthy of the E. F. Keating team 185. A great deal of pleasure has been derived from the social side of this tournament.

Thermostatic Draft Regulators.

The season is near at hand when those who deal in heating goods will no longer feel the rush of the past few months. This will reduce the current profits, but will allow ample time to push other profit earning specialties. As the season advances all who use heating apparatus of any character for warming their residences will find more or less trouble in keeping the fire regulated so that it maintains a steady temperature in the building. This condition of affairs can very readily be turned to profit if the suggestions presented in a little pamphlet entitled "A Domestic Sentinel," issued by the Howard Thermostat Company, Oswego, N. Y., are studied until they are thoroughly mastered and then brought to the attention of those who own hot air furnaces or heating boilers. This little pamphlet shows the different thermostatic regulators manufactured by this house, with all the working parts, and many illustrations making their application clear. The book also contains half-tone engravings of many fine residences in which the Howard system of draft temperature regulation has been used with satisfaction to the owners. There will be no occasion for a period of winter inactivity on the part of the dealer in heating apparatus if he will devote his time to the introduction and pushing of these comfort providing and fuel saving devices.

The Atlas Glass & Metal Company.

The Wheeling Hinge Company and the Wheeling Metal Company of Wheeling, W. Va.; the Republic Glass Company of Clarksburg, W. Va., and the Atlas Glass Company of Washington, Pa., have been consolidated into one company, to be known as the Atlas Glass & Metal Company, with headquarters at Wheeling, W. Va. Charles N. Brady of Washington, Pa., who is also president of the Hazel Glass Company, at Washington, Pa., is president of the new concern; W. S. Brady, who is president of the Fostoria Glass Company, at Moundsville, W. Va., is vice-president, and J. C. Brady, formerly secretary of the Wheeling Hinge Company, is secretary and treasurer of the new concern. It is the intention to manufacture at the Wheeling Hinge Company plant supplies and trimmings of all kinds for glass, but the business of the Wheeling Hinge Company will be continued as heretofore, it being run as a separate department, and the only change will be that some new and improved machinery will be installed for increasing their facilities, so as to enable the Wheeling Hinge Company to largely increase their output of hinges, bolts, nuts, washers and fire shovels and special stampings and forgings and such other goods as they have been making heretofore.

Heating and Plumbing Notes.

THE BUCKINGHAM-ROUTH COMPANY, New Haven, Conn., are installing an Ideal Water Heater in the St. James Parsonage, at Westville, and another Heater of the same type in the residence of W. J. Adams.

THE completion of the second sewerage district in Verona, Minn., has caused a rush in the plumbing business in that city, as house owners are desirous of having their drainage systems connected with the sewer before frosts sets in.

THE C. S. WENTWORTH COMPANY, Minneapolis, Minn., have the contract for heating the veterinary building at the State Farm.

THE contract for heating the Cathedral of the Immaculate Conception in Mobile, Ala., has been awarded to A. A. Aschaffenberg & Co. of New Orleans, at their bid of \$3075. A large steam plant will be used.

THE WESTERN PAUL STEAM SYSTEM COMPANY of Chicago have been awarded by the Board of Directors of the Indiana State Prison the contract to equip the prison heating plant with their system.

ROLLIN C. WILSON, 116 Nassau street, New York, has taken the sale of the Enameled Goods made by the Champion Mfg. Company of Blairsville, Pa., and will execute all orders for this class of goods in Eastern territory. The Champion Mfg. Company make a full line of Enameled Goods, including Lavatories, Sinks and Range Closets, together with four styles of Tubs of the popular designs. They have a catalogue in course of preparation, and as soon as it is issued it will be mailed promptly to the trade. Mr. Wilson has also added to his line Bath Wastes, Bell Supply Fittings, Basin Wastes, Lavatory Legs, Combination Low Down Fixtures and Low Down Brass Basins with china indices. He sells to the jobbing trade exclusively, and quotations will be made only upon application.

THE matter of providing plumbing instruction has received a great deal more of attention in Great Britain than in this or any other country. According to the latest available statistics there are now 26 plumbing classes carried on in the different cities and towns in England and Scotland, some of them being of considerable size and importance. Possibly the most important of these classes is that conducted at the Regent street Polytechnic, in London, where, since the plumbing classes were opened in 1882, no less than 2144 students have been given instruction. Of these 602 have passed the required examination and received diplomas. Most of the British plumbing classes are carried on directly under the auspices of the Plumbers' Guild, or of the local master plumbers' associations, and the examinations are conducted under Government auspices.

THE KEYSTONE BOILER & RADIATOR COMPANY, Huntingdon, Pa., have recently equipped their plant with new machinery, which will increase their output.

THE business of the Limberg Enameling Company, Cincinnati, Ohio, has increased to such an extent as to cause consideration to be given the idea of enlarging the capacity of their plant for producing Enameled Bathtubs.

H. GILBERT HART of the Hart & Crouse Company of Utica, N. Y., manufacturers of the Royal line of Steam and Hot Water Heaters, was a visitor in New York City this week.

PATRICK E. GREENE, Hartford, Conn., is overhauling the ventilating system in St. Patrick's School house in that city.

DOWNNEY & BRENNAN, New London, Conn., have just finished the plumbing and are now installing two Steam Heaters in the new residence of J. A. Wilkinson. They are also placing a Steam Heater in the residence of B. F. Mahan and are doing the plumbing and furnace work in that of John Humphreys.

IN reference to the copper work and steam piping he has recently done on a new oyster steamer, Henry Beutelspacher of Bridgeport, Conn., informs us that the work was that of a regular coppersmith. After the heater, condenser, pumps, &c., were in place the copper-

smith took the necessary measures to make correct templates of the pipes, which were then made and bent, with the brass flanges brazed on the end, and all branches. The main steam pipe was made of copper, 3-16 inch thick, flanged, brazed and riveted according to the laws and regulations governing the equipment of steam vessels. The most important pipes are those from the steam engine to the pump, from the condenser to the heater, from the sea cock to the circulating pump, from the circulating pump to the condenser, from the condenser overboard, and from the condenser to the feed pump, besides other work of less importance. It is said that the vessel will be one of the finest of its class on Long Island Sound. The work of Mr. Beutelspacher is in keeping with the character of the vessel.

C. A. LADDEN, Chicopee, Mass., has the contract for plumbing and ventilating the primary school building in that town. He is also doing the plumbing and steam heating in the new residence of James Kenna.

A RATHER remarkable case of public sympathy for a plumber is reflected in the action of a jury in Spokane, Wash. A plumber had been fined in a Justice's court for doing plumbing work without having taken out a license. He appealed to a higher court, and his only defense was an attack on the constitutionality of the plumbing law. The presiding judge held the law to be constitutional, but, after giving the case to the jury, they deliberated on the evidence for two hours and then brought in a verdict of "not guilty."

A FIRE recently occurred in the plumbing shop of J. J. Powers, Second street, Troy, N. Y., doing slight damage.

ROBERT S. WATSON was appointed Plumbing Inspector of Bay City, Mich., on November 8.

E. L. JONES & Co., Dover, Del., have been awarded the contract for the Heating Apparatus required in the new dormitory at the State College for Colored Students.

C. H. LATHAM, Norwich, N. Y., has just finished the installation of two additional Furnaces in the Congregational church in that town. He also has the contract for placing two Furnaces in the High School Building.

FLECK BROTHERS, Philadelphia, Pa., manufacturers and dealers in Plumbers' Supplies, now occupy their large new warehouse at 46, 48 and 50 North Seventh street, built during the past year. The building and its appointments are modern in every detail.

THE PAGE BELTING COMPANY, Concord, N. H., manufacturers of Leather Belting and Mechanical Leather Goods and Mill Supplies, are now placing upon the market a line of Pump Valves, Washers, Cup Levers and goods of a kindred nature. So that they can supply the trade the company are going to make this a separate department of their business, and hope by concentrating the energies of this one department upon these goods of choice stock that they will be able to figure to advantage to the jobbing trade.

F. N. DU BOIS & Co. of New York City, in order to better facilitate their telephone service and make it more efficient for their customers and themselves, have recently put in a private branch exchange, connecting the different departments of their house. They have notified the trade that their new telephone number will be 4332 Eighteenth.

THE master plumbers of Spokane, Wash., are opposed to the city plumbing ordinances and have been endeavoring to get a suit before the Supreme Court to test their legality.

CHARLES F. HAUSS arrived in New York on the steamer "Patricia" on Monday after having spent several months among the foreign heating trade.

THE new Walker Steam and Hot Water Boilers have had their merits brought to the attention of the trade since John A. Fish, who is well known to the trade throughout the country, has been made the manager of the wholesale boiler department of the Walker & Pratt Mfg. Company, 31-35 Union street, Boston, Mass. Mr. Fish has recently sent to the trade a letter asking that careful notice be taken of the grate area, heating surfaces, depth of fire box, and the ease with which all of

the heating surfaces in these new Boilers can be cleaned. He also calls attention to the conservative rating given the company's Boilers, pointing out that they can be safely relied upon, as they are based on what he terms "honest measure." Mr. Fish recently made a somewhat extended trip throughout the country, but naturally could not visit all of his friends, and he hopes those who have not been visited and who have not received a catalogue and price-list of the Steam and Hot Water Heating Goods made by his house will correspond with him.

JESSE PERKINS, City Plumbing Inspector of Niagara Falls, N. Y., who was also appointed Sewer Inspector last summer, has been granted an extra compensation of \$25 per month by the city Finance Committee for the additional duties imposed upon him.

W. F. DEADY has been awarded the contract for plumbing a new school house at Northbridge, Mass., at his bid of \$1270.

R. G. PARSONS, secretary of the Department of Public Works, Buffalo, N. Y., will receive bids until November 29 for the heating and ventilating work required in a 17-room school house in that city.

It is probable that the Warren plant of the National Tube Company, at Warren, Ohio, which has been idle for some months, will be started up before long. The plant was recently visited by a number of officials of the National Tube Company, in connection with W. L. Kaufmann, manager of the Youngstown district, and it was found that with some slight repairs it could be started up in a short time.

THE UNIVERSAL SANITARY WARE COMPANY have just started up their new plant at New Castle, Pa. The plant is not entirely completed, but parts of it have been put in operation.

THE TOLEDO CHANDELIER COMPANY have now been in existence three months, at Toledo, Ohio, and are running their plant with 40 men, night and day.

The Committee on Buildings of the Board of Education of the City of New York will receive bids until December 2 for installing heating, ventilating and electric lighting plants in Balzer Hall, at Grant and Prospect streets, Brooklyn.

THE DWYER PLUMBING & HEATING COMPANY, Minneapolis, Minn., have the contract for 4500 feet of Cast Iron Pipe for the water main which will connect the St. Cloud Reformatory with its new water supply.

DAVID M. NESBITT of the house of Ashwell & Nesbitt, Limited, London, heating and ventilating engineers and contractors, who has been spending a few weeks very pleasantly in the United States, gave a farewell dinner to a few of his friends at the Hotel Imperial, New York, previous to sailing to-day on the steamer "Etruria" for home. Among those present were: W. M. Mackay, secretary of the American Society of Heating and Ventilating Engineers; Henry B. Gomers, secretary of the National Association of Master Steam and Hot Water Fitters; E. D. Smith, Enoch Rulzter and Timothy Kieley of New York and Andrew G. Paul of Boston.

New Firms and Changes.

GEORGE TALBOT has opened up a steam and hot water heating business at 28 Portland street, Boston, Mass.

THE SAFETY GAS SHUT OFF COMPANY of Amesbury, Mass., have been incorporated with a capital stock of \$200,000. Patrick H. Connor of Amesbury is president, and John J. Linehan of Haverhill is treasurer.

EDWARD A. CATTON, formerly with Thomas R. Catton, has opened a plumbing shop at 195 Columbus avenue, New Haven, Conn.

RAY M. CHESNUTT, formerly of Brookville, Pa., has gone to Jacksonville, Fla., where he will engage in the plumbing business.

TRUMBORE & CHRISTERN, Stroudsburg, Pa., who have been doing a plumbing and steam fitting business in that town, have dissolved partnership, Mr. Christern retiring from business.

THE H. G. VOLKMAR COMPANY of New York City have

been incorporated to carry on a plumbing business, with a capital of \$5000. The directors are H. G. Volkmar, Louis Winterhalter and H. W. Volkmar.

THE SAFETY BRIGHT LIGHT COMPANY of Peoria, Ill., have been incorporated, with a capital stock of \$5000, by Charles J. Puffer, Peter J. Fagot and Joseph E. F. Fisher.

THE TRACY PLUMBING COMPANY of New York City have been incorporated with a capital stock of \$5000. The directors of the company are T. J. Tracy, A. B. Foans and O. A. Samuels of New York City.

THE SCHWAB BROTHERS COMPANY of New York City have been incorporated to deal in Plumbers' Supplies with a capital of \$25,000. The directors are Paul Schwab of Jersey City, Adolph Schwab of Bayonne and T. A. McKennell of Mount Vernon.

THE NEW CENTURY CAR HEATER COMPANY, with principal office at 243 Washington street, Jersey City, N. J., have been incorporated to manufacture Car Heaters with a capital stock of \$200,000 by Herbert H. Shannon, Edward S. Carr and Henry C. Shannon.

Improper Chimney Construction.

Every heating contractor is aware that the chimneys constructed in many buildings are utterly unfit for the work expected of them. This is due in some instances to ignorance on the part of builders, but quite frequently to indifference as to the operation, where a saving in cost can be effected for the builder and also a saving in space. An experience with such a chimney recently came up in the business of the Æolipyle Company, 237 Water street, New York, through a change in the ownership of a property. When it became necessary to fire the steam heater the new owner found it was impossible to get up steam. In his search for a remedy he was advised to secure one of the Æolipyle combustion governors, and this led him to arrange for a representative of the manufacturers to visit the building and arrange for the connection of one of their devices. An examination showed a vertical sectional steam boiler having several square feet of grate surface connected by means of a 10-inch pipe with the chimney. The dull, lifeless appearance presented while there was fire in the boiler led to a further examination of the chimney, when it was discovered that the flue was $2\frac{1}{2} \times 16$ inches in size, or utterly inadequate for the work it was expected to perform. A flue of such dimensions is of a shape calculated to offer most positive interference to the travel of air, gas and smoke through it. In this instance the flue backed up against another flue of the same size in an adjoining building owned by the same party.

On seeing the flue the chimney expert stated that it was useless to attach any apparatus to the heater with the object of securing its satisfactory operation. He recommended that the chimney be torn down from top to bottom and a chimney erected in its place with two flues side by side, having dimensions at least 9×9 inches, and preferably 8×12 inches in size. A new experience was then in store for him, for he was informed that this flue had been used the previous winter and that no difficulty had been experienced in getting up steam. In the presence of the owner the janitor testified that such were the facts.

Naturally, there is but one thing to do in such a case, and that is to leave it severely alone, which leads to the suggestion that possibly the janitor was afraid that if he admitted the flue was useless he would lose his position, by making it necessary for the owner to go to such a great expense as the construction of a new chimney would necessitate.

A novelty in architecture is a building to be erected at the great Dusseldorf Exhibition for next year. The building is intended to show the products of an asbestos manufacturing establishment, and is a picturesque cottage of half timber work, the panels between the timbers filled with sheets of asbestos, with sheets of cork fabric inside. Construction of such material makes a warm house.

ADVANTAGES OF TIN ROOFING.

Every one is more or less anxious to live under his own roof, but in spite of this desire most people in planning their houses pay less attention to the kind of roof that is to cover them than to any other part of the house. This should not be. If it is necessary to have a good foundation, then it is just as essential to have a good roof. It is the covering and the protection to the rest of the building. It is far more exposed than the walls. When the roof is damaged all the other parts are more or less affected. Hence the advice, "Look well to the roof in erecting a house." It cannot be too strongly impressed upon both builder and owner.

When constructing the roof of a building, says the *Architects' and Builders' Journal*, the material used should always be of the best quality and of the most serviceable kind. Terne plate (roofing tin) of good, trustworthy quality is the ideal roofing material, embodying all the characteristics that are requisite for a perfect roof covering. Roofing tin is practically impervious to all the external and internal attacks to which a roof is exposed. Roofing tin will not freeze in cold weather; it will not get soft in the hot sun. It withstands the destructive ravages of a storm. It is noncombustible. The licking flames of a conflagration cannot feed upon it. It acts as a conductor of lightning in connection with the spouting. Roofing tin is light in weight, and therefore adapted equally well for stone, brick or frame buildings. It does not absorb the dampness. It will not break if a stone or a limb of a tree falls on it. It is suitable for roofing under all possible conditions, from the flat to the steepest pitched roof.

FIRE RESISTING QUALITIES.

The greater safety of a tin roof is proved by the fact that the insurance rates on buildings covered with tin are less than on buildings covered with any other material. An experience of 50 years has demonstrated its value. None of the many other materials which are offered for roofing purposes possess the universal advantages of tin roofing. The inflammable wooden shingle, the heavy and porous tile, the breakable slate, the dangerous paper and the cheap gravel all possess disadvantages which are fully overcome by terne plates of good quality. The large majority of good architects and builders strongly favor terne plates (roofing tin) as the best material for roofing, provided they can be assured that the quality is first class and that good workmanship is employed in the construction.

HIGH GRADE PLATES ESSENTIAL TO A GOOD ROOF.

With the established fact that a roof constructed of good terne plate is far superior to any other kind of roof, it must nevertheless not be overlooked that even a tin roof may under certain circumstances prove to be a bad one. There are two causes which may produce such a result; either the plates are light and common or the workmanship in laying the roof was poor. Some years ago there was quite a demand for cheap material for small dwellings erected by contract and bonus builders. It was not unusual for large quantities of inferior material to be used for roofing in order to reduce the cost, and the anxiety of contractors to take work at low prices induced many to use the cheapest material possible. The evil results of this move have made themselves apparent. Some cheaply constructed roofs have decayed by reason of the false economy practiced in their construction and neglect of future care. Proof is furnished that material higher in price and first class in quality would have been decidedly the cheapest. Fortunately conditions have changed again. The general prosperity of the country and the practical spirit which is animating the American public is now more than ever manifesting itself, and the general demand is for materials of the highest grade.

AMERICAN TERNE PLATES.

The American tin plate manufacturers, who in the short space of ten years have succeeded in building up a tin plate industry larger than that of any other country in the world, are ever anxious to satisfy the demands of the people. American products in this line are admitted to be the most excellent the world over, which

fact was recognized by the International Board of Judges of the "Exposition Universelle," at Paris, when they awarded to American tin and terne plates the first prize. Any one who desires to have a perfect roof can obtain it if he but goes to the trouble of making sure that he gets the proper quality of material purchased from reliable dealers and put on by experienced workmen. The American tin plate manufacturers, with their unequaled facilities in their vast resources and the best obtainable skill in the manufacture of terne plates at their command, have made a special study of the roofing plate branch of the business. The result is that to-day American tin plates stand pre-eminent.

Different qualities of terne plates may be used in different districts. A quality of roofing plate suitable for one district may be totally unadapted for another district. But to meet all conditions terne plates are made to-day that will stand any climate. But observing the truism that the best is the cheapest in the end, none but the best qualities should be used in all cases, and if this rule were adopted universally all objections and prejudices, if any, which may exist in some localities against tin roofing would soon disappear. Roofs made from good plates, however, may be spoiled by bad workmanship. To guard against this the following suggestions are offered, the observance of which is of the utmost importance in the proper construction of tin roofing:

STANDING JOINTS VS. FLAT SEAM.

Steep tin roofs should be made with standing joints. By using the patent soldered standing joint you can avoid having steep roofs, as sufficient fall only need be given to allow the water to flow off gently. You also gain more room inside the building, which is greatly desired. No place for dirt to accumulate and rot the top of the joint, as in the old way. Only roofs with less than one-third pitch have heretofore been made with flat seams, and sheets 14 x 20 inches used, because the larger number of flat seams made in this manner stiffened the surface and prevented buckling and rattling in stormy weather. The disadvantages, however, in using a flat seam are it is more difficult and more seams to solder, besides there is no room for contraction and expansion, which causes the seams many times to open in hot and cold weather and leak in bad weather.

Steep tin roofs are covered with 20 x 28 terne plates, with standing joints. This allows for contraction and expansion, but must be made steep to prevent the water from rising over them and causing leakage, to overcome this disadvantage, however, and have a perfectly water tight roof. The patent standing soldered joint, which expands and contracts, the latest improved and best way of putting on a tin roof, supersedes both. You can have your roof perfectly flat if so desired. It cannot leak.

CHEAPEST TO USE BEST GRADE PLATES.

If you want the best as well as a durable roofing plate to cover your house with, use old method heaviest coated ternes, and when put on by good and reliable workmen a roof of this kind is good for years, and with proper care will outlast and in the end cost less than any other style of roofing. The larger the sheets, properly cleated not over 7 inches apart, and not less than four to a sheet of 20 x 28, and the fewer cross seams will make the best roof. While it is always cheapest to use the best materials, you may, when a cheap roof is required for reasonable service, use a cheaper terne plate, with less coating, but put on with the standing joint. For general roofing IC terne plate, in which the iron body weighs 50 pounds per 100 square feet, is more suitable than IX, as it can be worked closer and makes the best job, besides the seams in the lighter plates will not suffer as much from contraction and expansion as the thicker plates. The amount of terne coating on the lighter sheets should in all cases be fully as heavy as on the heavier plates. For spouts, valleys and gutters heavily coated IX terne plates of the very best quality should always be used, and are the best for these purposes.

USE NO ACIDS.

The use of acids or flux in soldering seams of a tin roof should be carefully avoided. Acids coming in contact with the bare iron on the cut edges and corners where the sheets are folded and seamed together will

cause rusting. Good rosin only should be used. Roofs should be carefully cleaned, and all rosin spots and detrimental substances should be removed as the tinner's work is being finished. Lumps of rosin left on the roof will melt in the sun, stick to the roof, cause blisters in the paint and prevent it from adhering. For valleys, spouts and gutters of a tin roof no other metal than terne plates should be used, because the galvanic action produced by different metals coming in contact with each other will cause disintegration under atmospheric influences.

The sheathing boards covering the roof should be put close together. The wood should be well seasoned and as free from knots as possible. It is also advisable to cover the boards with good roofing paper before the tin is laid. The tin should in all cases be painted before it is laid and fastened to the roof, as this prevents sweating. The outside should receive one coat of paint as soon as the roof is finished and another a month or so later. To make tin roofs last for generations they should be repainted every three to five years, in the fall or early spring, with a good iron oxide and red lead or pure silica graphite paint mixed with boiled linseed oil thoroughly mixed and evenly applied. The frequency of the intervals must depend largely on the climatic conditions of the country.

THE PASSING OF THE OLD TIME TINMAN.

BY R. IME.

The old time tinman is no more,
For, as tinware now is made,
The modern drop press has the drop
On him, and on his trade.

No more in every tinker's shop
Throughout this hustling land
Does he draw weekly wages
For making ware by hand.

In fields where he was once supreme
A boy now turns a crank,
And grinds out wagon loads of ware
With every lusty yank.

Now, too, the metal jobber has
Supplanted him, so that
The old style, ancient tinman
Hardly knows where he is at.

Where once ten hours made a day,
The rule has changed of late;
Hence the boss must make it pay,
Though "Jours" now work but eight.

Around the tinman's former haunts
No charcoal fires are seen;
Instead, a blue flame roars like h—,
'Mid smells of gasoline.

Forgotten are the tales he told
Of some famous big day's work,
But clear is still the memory
Of his ability to shirk.

The old time tinman is defunct,
His days are filled with woe,
Since machinery hath dealt to him
A solar plexus blow.

Furnace or Heater Pipe Tin in Rolls.

Wheeling Corrugating Company, Wheeling, W. Va., and 47 Cliff street, New York, have just put on the market heater pipe tin in rolls for the convenience of tinsmiths and others who manufacture furnace or heater pipe of tin. The metal is seamed together in lengths 120 feet long and 20 inches wide, each length containing 200 square feet, either IC or IX tin. The material is packed for shipment in sheet iron casks or cylinders with wooden heads, so that it is well protected until needed. An important feature of this product is that the

workman is always prepared to make up any diameter of pipe from one bundle of each grade of stock, instead of being compelled to carry tin plates in boxes of the various sizes needed for each diameter, some of which are seldom used.

The H. W. Johns Paint Mfg. Company.

The H. W. Johns Mfg. Company, manufacturers of asbestos roofing, roofing felts and coatings, sheathings of all kinds, asbestos packing, asbestos cements, &c., whose main offices are at 100 William street, New York, announce to their customers that their paint business has been incorporated as a separate organization, and will hereafter be known as the H. W. Johns Paint Mfg. Company. The officers of the new company are H. W. Johns, president; G. W. Gladwin, vice-president; F. R. Boocock, treasurer, and John S. Mowry, secretary and general manager. These gentlemen have long been identified with the manufacture and sale of H. W. Johns liquid paints, and their customers are therefore assured that the same high standard of quality for which their paints were justly celebrated will be fully maintained.

The purpose of the reorganization is to place the paint department of the concern on an independent basis, and thereby enable that department to more thoroughly push the sale of their paint products. The change took effect on and after November 18, 1901. All correspondence referring to paint should be addressed to the new company, 100 William street, New York.

All accounts receivable to and including November 16, 1901, will be made to the H. W. Johns Mfg. Company, and all accounts payable for the same period will be made by the same company. After the date specified both accounts receivable and payable will be assumed by the H. W. Johns Paint Mfg. Company.

The Use of Roofing Tile Abroad.

In describing the manner in which roofing tiles were used in Greece and Rome, a writer in an exchange states that flat tiles with raised edges extended from rafter to rafter, the upper end having a rib which entered a groove formed on the under side of the tile placed above it. After these were laid the joints above the rafters were covered with other tiles, each formed like the half of the frustum of a hollow cone, so that they were able to lap upon each other, their edges lying snugly to flat tiles on the roof. The end of these ridges was terminated with an ornament. Tiles, both flat and curved, were in great demand in Roman architecture. Roofs were covered with the flat and curved tiles alternating. Tiles 2 feet square, with a foot at each angle, were used to line the thermæ, so that an air space between them and the wall should prevent the absorption of water by the latter.

FLASHINGS

JOHN H. MORGAN of Cambridge, Ohio, one of the national trustees of the Amalgamated Association of Iron, Steel and Tin Workers, will, it is said, be appointed Chief State Workshop and Factory Inspector of Ohio.

EUGENE W. PARONY, one of the district managers of the American Sheet Steel Company, sailed last week for Europe.

THE ALAN WOOD IRON & STEEL COMPANY of Philadelphia, Pa., have been incorporated with a capital stock of \$1,250,000. The company will take over all the Alan Wood properties at Conshohocken, Pa.

THE Sheet Bar mill at the Midland Steel Works plant of the American Sheet Steel Company, at Muncie, Ind., will be placed in operation shortly. The mill was shut down about six months ago, it was supposed permanently, but the scarcity of Sheet Bars has made it necessary for the company to place it again in operation.

THE latest advices from England report that although, up to the present, the production of Tin Plates in that country is not in excess of requirements, as many of the Welsh works are still employed on contracts made with American buyers in the early stages of the Steel strike in this country, it is feared that the demand

for Welsh Tin Plates will soon fall behind the production, which is now large, a number of idle mills having been placed in operation.

THAT architects, builders and owners appreciate a Roofing Tin having genuine Charcoal Iron base is evidenced by the fact that there is a large and growing demand for this class of Roofing Tin. The J. M. & L. A. Osborn Company, Cleveland, Ohio, placed upon the market some years ago a Roofing Tin with a Charcoal Iron base. This concern report a steady and increasing demand for this grade of Plates, Osborn's Charcoal Iron Old Style Terne Plates being frequently specified where the best material is desired. The company have recently shipped 35 boxes of IX, 20 x 28, Plates to Detroit, Mich., for a large church building in that city. While in the past it has been found difficult to secure ample supplies of Charcoal Iron Sheets for making up these Plates, the J. M. & L. A. Osborn Company now assure us that the Sheets can be secured in sufficient quantities for all requirements.

JONES & HOPKINS, Nashville, Tenn., have a contract, amounting to nearly \$1500, to put a Slate roof on the new municipal electric plant of the city of Nashville. They have also just taken a contract for roofing the new building of the Fire Department of the city. The firm have several other roofing contracts in hand, and are enjoying an exceedingly good trade in their Stove and Range departments. They employ 30 hands.

W. T. GUMMEY of Gummey, McFarland & Co., Philadelphia, Pa., paid a visit to New York City this week and met a number of his friends in the Metal trade.

THE GRIFFITHS CHARCOAL IRON MILLS of Clinton Township, Washington County, Pa., have been incorporated with a capital stock of \$200,000.

It is reported that negotiations are on foot with the Board of Trade of Wheeling, W. Va., for the establishment in that city of a new eight-mill Sheet plant.

THE SOUTHERN CAN COMPANY of Baltimore, Md., have been incorporated by Samuel H. T. Hayes, Robert B. Schurger and others, with a capital stock of \$5000, to manufacture Tin Cans.

ALBERT F. BAUMGARTEN of Pittsburgh, Pa., has purchased the plant of the Crucible Steel Company of America at Cumberland, Md., and will, it is said, operate it as a Sheet mill.

W. S. BULLARD, Hartford, Conn., is doing the roofing on the new buildings of the Ordnance Company, in that city, and on an addition to the factory of J. S. Fray & Co. He has also the contract for the roofing on the new buildings of the Deoxidized Brass & Copper Company.

DEETZ & Co. built last spring a suitable plant for their business at 408 West Superior street, Duluth, Minn., and during the summer they did a heavy business in Pitch and Gravel Roofing, and in Tin and Sheet Iron Work. The company's Sheet Metal shop is well equipped with modern machinery, and their contracts have extended over Minnesota and the Dakotas. A. W. Deetz, who is the manager of the business, has had 20 years' experience in the field. The firm now have contracts for work on the St. Luke's Hospital, the Polish Roman Catholic Church, a Jewish Synagogue, the Northern Pacific freight house, the Peavey Cement Elevator and the car shops at Proctor's Point. They are also doing the ventilation work at the Normal and High School buildings at Two Harbors, using Globe Ventilators.

GUMMEY, MCFARLAND & Co., Philadelphia, Pa., have recently booked large orders for their Genuine Anti-Pinhole Charcoal Iron Tin Plates. Architects, they advise us, are specifying these Plates in many instances. One entire block in Detroit, Mich., is to be covered with these Plates, as is also the roof of the Masonic Temple in Danville, Ind.

FORMER employees of the Star and Monongahela tin mills of the American Tin Plate Company, at Pittsburgh, by a vote of 197 to 3, have rejected the proposal to open these mills to members of the Amalgamated Association. It will be recalled that before the strike was ended both these plants were started up with non-

union men, and the Amalgamated Association is no longer recognized, and no members of that organization can work in either of these mills and be a member in good standing. Both plants are in full operation, and have been for a long time.

THE CHATTANOOGA STEEL ROOFING COMPANY, Chattanooga, Tenn., are now, as during the whole of this year, very busy filling contracts for Roofing and their other lines, for home and export trade.

CHARLES M. SCHWAB, president of the United States Steel Corporation, has agreed to donate \$50,000 toward the erection of a Y. M. C. A. building at Vandergrift, Pa., where the largest of the Sheet plants of the American Sheet Steel Company is located.

THE men employed in the Monongahela Works of the American Tin Plate Company, on the South Side, Pittsburgh, are still annoyed a good deal by the strikers, and recently it was found necessary to ask for additional police protection for the men.

The Zinc Smelting Corporation.

Details of the plan to consolidate the large zinc smelting companies in the Missouri district have just leaked out. We are informed, through authoritative sources, that options have been secured on all the plants mentioned below, and that E. Rollins Morse & Bro. of 6 Wall street, New York, are conducting the details of the proposed consolidation. The company are known as the Zinc Smelting Corporation, with offices at 1 Exchange place, Jersey City, N. J. The company were organized under the laws of the State of New Jersey with a capital of \$50,000,000, divided into \$25,000,000 of 7 per cent, cumulative preferred stock and \$25,000,000 of common stock, \$5,000,000 each of the common and preferred stock to be reserved for the acquisition of properties in addition to those already contracted for, and for other corporate purposes.

The company have contracted for the acquisition of the Illinois Zinc Company, George E. Nicholson, Vulcan Spelter Company, Empire Zinc Company (Joplin, Mo., plant), Matthiessen & Hegeler Zinc Company (half interest), James La Tourette, S. H. Lanyon & Brother, Lanyon Zinc Company, A. B. Cockerill, Prime Western Spelter Company, Collinsville Zinc Company, St. Paul Mining Company, Kansas City Mining & Spelter Company, Cherokee-Lanyon Spelter Company, Girard Zinc Company and Bruce Mining & Smelting Company.

It is expected that, with ample working capital and through efficient management and numerous economies, the profits of the corporation will be largely increased beyond the combined profits of the individual plants, and with the present capacity and present market and consumption it is expected that the profits of the Zinc Smelting Corporation, from the production of spelter, zinc and sulphuric acid will be close to \$4,000,000 annually.

The present production of spelter in America the prospectus states is about 140,000 tons per year, most of which has been consumed at home, over 60 per cent. being consumed by the steel and wire industries. Heretofore, it says, the exports have gradually increased, but during the present year the home consumption has been practically equal to the production. The European production is given as about 380,000 tons annually, and the consumption as fully 400,000 tons. The cost of production in Europe is placed at over \$10 per ton more than in America, and the consumption per capita is more than 25 per cent. greater.

Manager A. R. Hunt of the Carnegie steel mills, at Duquesne, Pa., announces that the month of October was the greatest in the history of the works in regard to the output of iron and steel. In the Bessemer department 55,521 tons of steel were produced, which is 2332 tons above the world's record for one month. In the open hearth department 40,321 tons of steel were turned out, which is 1917 tons over the world's record, and at the 21-inch mill 51,936 tons of billet steel were made, being 3859 tons above the world's record.

The Brohard Expansion Bolt.

The Brohard Company, Philadelphia, Pa., are placing on the market a new expansion bolt, illustrated herewith. The device is manufactured of malleable iron and is designed particularly to provide a bolt, having an expansion cover, capable of easy insertion and removal from fixed positions in the wall or other place where it is to be used and which will remain in that fixed position. The parts of the expansion bolt are few, and are so arranged that they cannot become detached from each other. The driving head or spreader is cone shaped and is in contact along its whole length with the expanding sections of the sleeve. It is held in position by means of suitable lugs or ribs, which are dovetailed into the slotted sides of the expansion case, making it impossible to force the spreader or drawing head from the case. The company are now prepared to furnish these

The Brohard Expansion Bolt.

bolts in sizes $\frac{1}{4}$ to 1 inch diameter, and from $1\frac{1}{4}$ to 12 inches in length, larger and special sizes being made according to order and specifications.

Gas Made from Air.

According to Raoul Pietet, the famous Swiss inventor, his latest discovery in regard to the manufacture of oxygen gas is likely to revolutionize the metal trades and have an important influence on most of the industries. Briefly the invention consists of taking oxygen out of the atmospheric air by physical means, and not by a chemical process, as at present. The inventor claims that by this process the cost of oxygen will be less than $\frac{1}{2}$ cent per cubic foot, which, compared with present prices, is in the proportion of 1 to 50.

The process will be applied to metallurgy, chemistry, lighting and public health. For lighting purposes the oxygen will be mixed with the water gas, and, it is said, will give a much better light at a much lower price. It has great heating properties and can be used for smelting all ore containing gold and other refractory ores. The process, it is said, will be much cheaper than any present one for sanitary purposes. The oxygen can be put into large rooms, schools, theatres and so forth, and by this means the air will be rendered much purer.

The money in circulation in the United States on November 1 was \$2,246,300,000, or \$28.72 per capita. This is the highest point reached, both in volume of money and in the amount per capita, also the largest sum of money in circulation in any country in the world, and the largest per capita of any country except France.

The National Founders' Association.

The fifth meeting of the National Founders' Association, which was held last week in New York City, brought together a large number of the members. The meeting was one of the most interesting and successful ever held. Among those who attended the meeting were W. H. Phaler of the Abram Cox Stove Company, Philadelphia; C. A. G. Winther of the Chapman Valve Mfg. Company, Indian Orchard, Mass.; W. S. McMullen of the Richmond Stove Company, Norwich, Conn.; John M. Taylor of the Dominion Radiator Company, Toronto, Ontario; Alex. Jarecki of the Jarecki Mfg. Company, Erie, Pa.; Matthew Griswold and Matthew Griswold, Jr., of the Griswold Mfg. Company, Erie, Pa.; W. L. Herendeen of the Herendeen Mfg. Company, Geneva, N. Y.; F. A. Strong of the Eaton, Cole & Burnham Company, Bridgeport, Conn.; Thomas Devlin of Thomas Devlin & Co., Philadelphia; H. Van Atta of the J. L. Mott Iron Works, New York, and Stanley G. Flagg, Jr., of Stanley G. Flagg & Co., Philadelphia.

An elaborate and interesting address and report was presented by President H. W. Hoyt, who reviewed in an able manner all of the important phases of the secret work of the association and gave his views as to the most expeditious method of solving problems before the association. The report of Treasurer John R. Russel showed the association to be in a sound financial condition, and Secretary John A. Penton read an exhaustive report in which he outlined the successful achievements of the association, particularly in the manner in which they had been able to adjust disputes with employees. Several interesting papers were also read and discussed.

The following officers were elected for the ensuing year:

President.—W. D. Sargent, the Sargent Company, Chicago, Ill.

Vice-President.—F. T. Towne, Yale & Towne Mfg. Company, Stamford, Conn.

Treasurer.—John R. Russel, Russel Wheel & Foundry Company, Detroit, Mich.

Secretary and Commissioner.—John A. Penton, Detroit, Mich.

At a banquet at the Gilsey House President Hoyt was presented with a magnificent sterling silver tea set and salver consisting of seven pieces, the salver bearing an inscription showing the appreciation of the association for Mr. Hoyt's services as president. The Cleveland and Lorain foundrymen also presented to Secretary Penton a chest of sterling silver knives, forks and spoons, containing 139 pieces, as a token of their esteem for his services in the interests of the foundrymen in the great molders' strike in those cities last year.

Industrial Crisis in Austria.

United States Deputy Consul-General Simon W. Hanauer, at Frankford-on-Main, reports that accounts from Prague, Bohemia, state that industrial conditions in Austria are going from bad to worse. The Bohemian rolling mills have been forced to discharge a large number of hands. The Prague Iron Industrial Company, as also the Bohemian Mining Company, two of the most extensive works in Austria, have also reduced operations, discharging a large force of workmen. Several hundred operatives were discharged at the iron works in Kladno and Teplitz, Bohemia. The sales of the combined works belonging to the Austrian syndicate during 1900 were 62,000 metric tons less than in 1899, and it is estimated that they will shrink much more this year. Their sales comprised 305,000 metric tons in 1899. Germany was a large customer for this Bohemian iron. The depression in that country curtails the sales, and the demand from domestic (Austrian) machine and bridge building works has almost ceased.

An effort is to be made to remove a large red oak tree from one of the wildest sections of Arkansas to the site of the coming exposition in Forest Park, St. Louis, Mo., without injuring it. The tree is 100 feet high and

12 feet in diameter at the base. A double tramway is to be built from the tree to the river, where it will be floated and towed to St. Louis. It is estimated that the work will occupy six months.

Give Street and Number in Address.

The extent to which correspondents omit the number and name of the street when giving their address is the cause of no little trouble and annoyance to those receiving their communications. Many writers also appear to labor under the impression that there is only one city or town bearing the name of the place in which they live, and that therefore there can be no possibility of any mistake on the part of the recipient as to the proper address. In this they grievously err, as a casual examination of a United States Postal Guide will quickly show. As indicating in some measure the extent to which this form of annoyance is carried, we present below a letter from a gentleman who has business dealings in many cities of the Union, and who, as a consequence, is in receipt of letters from widely scattered sections. Among other things he says:

"Any one will notice from even a casual examination of the letter heads of many firms, and even of private individuals, that in perhaps the majority of cases they omit the street and number in their address. Sometimes they give the number of the room in a public building where their offices are located, but often they simply give the name of the building, with no further address except that of the city and State. Now, this may be all well enough for a citizen in their locality, but when a stranger desires to see these parties, or writes them, it is another question.

"In correspondence, usually the name of a building is a long one, and it takes a great deal of time to write it out, and one is more apt to make a mistake. For example, I correspond with parties in the 'Metropolitan Life Insurance Company Building,' also with parties in the 'Keith-Perry Building,' whereas the number and name of the street would be more simple. Or, in another case, the person lives on the corner of 'Commonwealth avenue and Washington street.'

"Now in my travels I have visited many cities, trying to find people located in some of these buildings, and while in Cincinnati a short time since, with the letter head of the kind above mentioned in my possession, I asked a policeman where such a building was located, and he directed me some six blocks away. I showed him the letter head and spent about an hour trying to find the place, and to my surprise, as well as disgust, the building I was looking for was directly across the street from the corner where I asked the policeman. Now if the street and number had been on that letter head I would not have had to ask questions, and anybody could have directed me to the street, and it is only a question of intelligence to follow up the number.

"I spoke to a gentleman yesterday about this matter, and showed him his letter head, and he replied, as everybody does, 'Why, everybody knows where the Benedict Building is.' To prove this I asked a policeman and a hotel clerk and neither of them knew where it was.

"Now you see this takes a great deal of valuable time. People should give their number and street address. It saves time in writing it out and looking it up. It seems to me that this subject is an important one, and I trust others will express their views regarding it."

The United States Consul-General in Vienna reports that a committee composed of leading manufacturers, members of the Vienna Chamber of Commerce and representatives of prominent corporations, has just held a meeting in that city, at which the idea of an international exposition of inventions and novelties, to take place in Vienna in 1903, was discussed. The general scheme of the exhibition was unanimously indorsed, and the preliminary steps taken thus far toward its realization by the committee were approved. According to the programme as sketched out it is to embrace all

varieties of technical inventions and, in particular, those already practically introduced in the manufactures. There will, perhaps, be an inventors' gallery, where workshops will be open for public demonstration. The financial support of the undertaking seems to be assured. Great hopes are placed in the success of the exhibition, which Austrian gas and water men are especially active in promoting. From this inceptive stage this would seem to be an excellent opportunity for Americans to show their achievements in practical invention, a field that may be called almost pre-eminently their own.

The Defiance Grinding and Polishing Machine.

The machine here illustrated is equipped with a solid emery disk, set in a metal ring, which is used for grinding and truing up work. It is also fitted with two polishing drums, and a small round emery rod for polishing small curves. An emery belt can be used over the pulley at the base of the machine and the one underneath the table. The emery disk is 16 inches in diameter, and is provided with a swinging adjustable table

The Defiance Grinding and Polishing Machine.

which is planed true on top. It can be used to carry the work across the face of the disk, or as a stationary table. The polishing drums are 6 x 6 and 7 x 7 inches. The table over the smaller drum is provided with a vertical adjustment to regulate the depth of cut. The machine is built by the Defiance Machine Works, Defiance, Ohio.

THE ISLAND FOUNDRY COMPANY of Mechanicsville, N. Y., are sending out a neatly printed eight-page pamphlet of convenient size to carry in the pocket, calling attention to the Hot Air Registers and Ventilators which they manufacture. Numerous designs are illustrated, including the popular lattice style, the round slide center design, plain lattice pattern, circular top design finished in black or white japan and convex design for thin partitions, together with Ventilators to be operated by means of cords, and furnished in any style, design or pattern. Tables are given showing the sizes in which the various styles of Registers are made and the prices for different finishes.

THE BENEDICT & BURNHAM MFG. COMPANY, Waterbury, Conn., Brass and Copper rolling and Wire mills, have let the contract for the erection of an acid house, 50 feet square, of brick and iron construction.

There has recently been cut what is believed to have been the largest walnut tree in Ohio, and one of the largest now left in the country. This tree measured a little over 8 feet in diameter at the stump, and the body of the tree, suitable for cutting into logs, was 74 feet long. This will make two carloads of export logs, in addition to a large quantity of squares which will be cut from the limbs.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

PATTERNS FOR FLUTED BOTTOM OF CIRCULAR BAY.

From D. R., Troy, N. Y.—Will you kindly show me the way to lay out the patterns for the fluted bottom of a circular bay, as shown on the sketch which I send herewith?

Answer.—In the accompanying illustrations we have made a finished drawing from our correspondent's

it in the side view, placing the line G F in a vertical position, as shown by F¹, G¹, H¹ and J¹, letting the line K¹ L¹ M¹ represent the background, similar to K L M in soffit plan. Extend the line F¹ G¹, as shown by P R, which represents the wall line. From the front elevation project the heights of the moldings, as shown by the dotted lines S and T, and from L¹ in plan in side view, at right angles to H¹ J¹, erect a line intersecting the bottom of the cove at 5. Now, with the desired center as U, describe the arc 5 3, touching the desired points at top and bottom. This arc represents the background, to which the flutes should be soldered. This background will be made of flaring strips of metal, which can be raised if desired, but is unnecessary, because the flutes will cover the entire surface. For this reason divide the curve 5 3 into a number of equal spaces, to avoid sharp corners, as shown by the points a and b, thus making three flares, numbered 1, 2 and 3. To obtain the

PATTERNS FOR FLUTED BOTTOM OF CIRCULAR BAY.

sketch, in which A B C D E shows the front elevation of the bottom of the bay, and F G H the soffit plan struck from the center J on the line E C in elevation. Before the flutes can be placed in position a background must be made to receive them. The line of this background is shown in plan by the dotted line K L M, and shown approximately in elevation by the dotted line N O. These lines being established, divide the plan into the number of flutes desired, as shown, letting the circular heads or semicircles meet the dotted line K L M, as shown. From the plan project up the flutes in elevation, as shown. This is not necessary in practice, but is shown here to give a clear understanding.

The next step is to construct the side view, from which the radii and patterns are obtained. Take a tracing of the plan F G H, with the center point J, and place

radii for these three flares, draw lines through the points 5 a, a b and b 3, intersecting the line V W, drawn parallel to the line F¹ G¹ through J¹ at points c, d and e, respectively. From the points a and b draw horizontal lines, intersecting the center line H¹ J¹ in plan, as shown. With J¹ as center and through these intersections draw the arcs 1', 2' and 3', which correspond to the flares 1, 2 and 3 in the side. For the pattern for flare 1 proceed as follows: With c as center and radii equal to c a and c 5 describe the arcs 5 5' and a o'. As the point 5 in side view is shown in plan by the arc 1', divide one-half of the arc 1' into equal spaces, as shown by points 1 to 5, and set off double these spaces on the arc 5 5' on blank 1, as shown from 5 to 1 and 1 to 5'. From 5' draw the radial line 5' c, cutting the arc a o' at o'. As the wall

line $G^1 F^1$ in plan crosses the arc at other than radial lines, so will the end lines of the blanks be other than radial lines. Therefore, from 5 in plan draw a radial line to the center J^1 , and extend the arc $2'$ to o . As the arc $2'$ represents the plan line of the point a of the flaring strip 1, measure the distance $o n$ in plan, and place it, as shown, from o' to n' and a to n'' in blank 1. Then the portion shown shaded will be that part which will be cut off the pattern. In precisely the same manner will the blanks 2 and 3 be developed, using the centers d and e , respectively, on the line $V W$, measuring on the arcs $2'$ and $3'$ in plan for the lengths of the patterns. After the blanks are developed they can be soldered together, using the arcs shows in plan as stays. Thus the arc $K^1 L^1 M^1$ in plan is soldered to the top of blank 1, the arc $2'$ in plan to the top of blank 2, the arc $3'$ in plan to the top of blank 3 and the shaded portion of 4 in plan to the bottom of blank 3. This forms the model to which the flutes are fitted, after which they are raised. The model is now divided into equal spaces, as desired, and lines drawn, with crayon or marking acid, to the bottom, so that a line is obtained as a guide for raising and fitting.

In getting out the patterns for the flutes, they will only be approximate, as some metals will stretch more than others, according to the gauge in use, and will therefore require some trimming. With the model as above made an experienced hand would require no further stays, but would raise to the lines shown on the model. But one less experienced would require stays through the center of each one of the flutes in soffit plan, which would be tacked with solder in its proper position on the model and the flutes raised accordingly.

As these stays are also used for obtaining the amount of material for the flutes, we will show the method of obtaining the stay for the center flute X in soffit plan, and to avoid a confusion of lines, diagram E^1 shows a reproduction of the flares 1, 2 and 3 in side view, as shown by $1''$, $2''$ and $3''$ in diagram E^1 . It should be understood that this center flute X is the only flute on the bay which is symmetrical, all the others being cut by the arc $K L M$ at other than at right angles to their axis. For example, note the axis line $r s$ in the flute Y . Now draw the section of the flute X in diagram E^1 , as shown by 1 to 8, which also represents the stay. Divide the section into equal spaces, as shown by the small figures 1 to 8. Now draw any vertical line, as $L^1 M^1$, in diagram A^1 , upon which place the stretchout of the section of the flute in E^1 , shown from 1 to 5, as shown from 1 to 5 on $L^1 M^1$ in diagram A^1 . At right angles to $L^1 M^1$ and through points 1 and 5 draw the lines 6 6 and 7 7, respectively, making 6 6 equal to the stretchout of the semicircle L of the flute X in soffit plan, and the distance 7 7 equal to the stretchout of the flute X at its apex, shown in elevation at the bottom of J or measured direct from the model. From 6 to 7 on both sides in diagram A^1 draw slightly curved lines, as shown. Then 6 7 and 7 6 will be the pattern for the flute X in plan. This should be raised with the raising hammer and blocked until it fits the stay and model, as before explained, and will require a little trimming. In some shops the circular top of the flute is soldered separately to the flute by using a quarter ball. If care is taken this separate head can be soldered so that the seam will not be noticed; but to make a first-class job the circular head is hammered directly on the flute, by adding to the pattern in A^1 the semicircle 6 8 6, using 5 as the center. As each one of the flutes in plan becomes longer as they reach the wall line, it becomes necessary to obtain a true section through the center of each flute to obtain the amount of stuff required; also to use as a stay in raising. In this case four different stays would be required, and, for example, we shall show the method of obtaining the true section on $r s$ in plan, the same principles being applied to the other three. Therefore, through the flute Y draw the center line $r s$. Now, with radii equal to $J^1 1'$, $2'$ and $3'$ in plan in side view, and with J in front elevation as center, describe partial arcs in soffit plan, as shown by $1''$, $2''$ and $3''$, intersecting the line $r s$ at u , v and w . At right angles to $r s$ and from the intersections u , v , w and s draw lines indefinitely, as

shown. Parallel to $r s$ draw any line, as $B^1 C^1$. Now, measuring in each and every instance from the line $f h$ in diagram E^1 , take the distances to lines i , j and k , and place them on similar vertical lines drawn at right angles to $r s$, as shown by similar letters, h' , i' , j' and k' . Trace a line, as shown. Then $h' k' C^1$ will be the true section on $r s$ in plan. Around this section draw the section of the flute, as shown. Then in the same manner, as shown in diagram A^1 , obtain the approximate pattern, being careful to note that the length of the one side of the flute Y , shown from s to y , is greater than from s to x , as is also the case in the other flutes.

CONSTRUCTING A CHURCH FURNACE.

From John Kanuck, Connellsville, Pa.—Replying to the inquiry of "A. S.," in *The Metal Worker* of November 2, regarding the use of a box stove for a furnace, I would advise, don't do it, if you want a job that will be a credit to you and bring you further business. So far we have never seen a box stove that would stand

Constructing a Church Furnace.

the test of being inclosed in a brick air chamber and not become in a short time so badly warped and cracked by the heat that it would be useless, or nearly so. If, after he has considered this statement, he should still wish to use the stove, I would advise him to make two flat drums of nearly equal length and of the full width of the stove and about 5 inches deep. Connect the bottom side of the lower drum at the back with the stove by means of an 8-inch collar, long enough to raise this drum about 6 inches above the top of the stove. The lower drum should be connected with the upper drum at the front end by two collars, each 6 inches in diameter and long enough to leave a space of some 6 inches between the two drums. Two 6-inch collars can be put on the top side of the upper drum at the back, so as to receive a pipe to run to each of the two chimneys. I would also have a collar connecting the two drums at the rear end so as to secure a direct draft for starting the fire. In this collar I would place a tight damper with a rod running through the front brick work, so that by manipulating the damper a direct or indirect draft can be effected, as desired. The drums or radiator above the stove should be made heavy and tight, and they should have openings in the front end for removing soot and ashes and for general cleaning. These openings must be fitted with good tight covers so that air cannot enter to interfere with the draft. Build the brick casing of the warm air chamber so as to leave a space of 5 or 6 inches on both sides and the back end of the stove, and if possible have the roof of the air chamber 15 or 18 inches above the top of the radiating drum. I would place one register of ample size in each aisle of the church and connect it with the furnace with a pipe 18 inches in diameter. Each of these pipes should have a good tight damper in it very close to the furnace, so that these pipes can be shut off when the furnace is used for heating the basement. There should be two 18-inch collars placed in the brick work in the basement having tight covers on them, which are to be taken off when the Sunday school room is to be heated.

From G. R., Shoal Lake, Manitoba.—In answer to the letter of "A. S." in *The Metal Worker* of November 2, asking advice as to how to heat a church with a box stove, I beg leave to give him a little of my experience.

I would decidedly advise him not to connect the smoke pipe to two separate flues. He should make one flue take the smoke. If he uses two flues one will draw against the other, with the result that there will be no fire, but pails of condensation and soot. I would also advise him to use two registers, one in each aisle, and to place the furnace as near as possible directly under them, so as to make the hot air pipes short. They should be 14 inches in diameter and connect with 14 x 19 inch registers. I would also advise him to take two cold air pipes back from the church floor to the furnace and make them as short as possible. A ventilator should be put in the ceiling, to be opened when the church is too warm. An opening should be left at the bottom of the furnace to take cold air from the Sunday school room. I would advise a collar on the top of the furnace to allow hot air to come when the Sunday school room is to be heated. A horizontal drum should be placed over the top of the box stove, with a division in it to secure an indirect draft, and arranged with a damper to be operated when a direct draft is needed. A cold air pipe of ample size should be taken from the northwest quarter, and should have a slide to shut off when it is not needed.

CHIMNEY VENTILATORS FOR BACK DRAFT?

From C. E. M., Hanover, Pa.—I would like to ask for a remedy for a back draft to a chimney other than the one given to "Y. K.," in *The Metal Worker* of November 16. I have had a chimney that acts the same as the one described by "Y. K.," and I removed the stone slab from the top of the chimney altogether, but it did no good.

Note.—Those of our readers who make a specialty of dealing with troublesome chimneys are invited to give their views on this subject. It is probable that any of the several different manufacturers of ventilating chimney tops would recommend the use of some special form of chimney top, after they had determined the cause of the trouble. Naturally, a man at the place who can see the surroundings of the chimney and note the effect of trees, hills or buildings near at hand, can readily determine the movement of the air currents which interfere with the draft. If the trouble is most pronounced in strong winds there can be little doubt but that a ventilating chimney top so constructed as to create an exhaust draft will prove a remedy if properly applied to the chimney. There are some forms of chimney tops that are claimed to utilize the air which rises along the outside of the chimney top and becomes heated for entering through special openings and creating an exhaust current even in still weather. However, this is a subject which those who have had a long practical experience with chimney troubles can best discuss, and we hope that there will be no lack of assistance from such of our readers to this correspondent.

Power Development at Niagara Falls.

When, on October 4, 1890, ground was broken at Niagara Falls, N. Y., for the tunnel power development of the Niagara Falls Power Company, and the plans for the development were gradually unfolded to public view, it was generally recognized that it was destined to be a marvelous installation that would be erected to place the force of the river within the reach of man. The eleven years that have elapsed have served to meet all expectations in this respect, and it has been found that the 5000 horse-power turbines and the 5000 horse-power generators have answered the expectations anticipated of them. When these machines were built they were the peers of all that man had ever created. They denoted a remarkable progress, and from the time they were installed to the present day they have attracted the attention of scientists of the world.

Now a new development is projected for the Canadian side at Niagara, and the experience of years and the advancement in electrical science are to be drawn upon to make the proposed new Canadian plant a twentieth

century marvel. Acting upon the advice of Mr. Buek, electrical director, the Canadian Niagara Power Company have adopted plans for generators of 10,000 horse-power capacity each, and the General Electric and Westinghouse companies are figuring on them. Thus each of these generators will have double the capacity of the generators now in use in the station of the Niagara Falls Power Company. Further facts about these wonderful machines are not at this time available. The tunnel work on the Canadian side is going forward rapidly, and the contract for the new wheel pit will be awarded, in all likelihood, within the next fortnight.

That there is continuous progress in the electrical line is evident from the fact that the new generators the General Electric Company are now building for the Niagara Falls Power Company are guaranteed not to short circuit. This is a feature of vast importance, for the short circuiting of the 5000 horse-power dynamos is the greatest source of danger in the station, and only recently one of the big dynamos was burned in this way.

William B. Rankine, vice-president of the Niagara Falls Power Company, and other officials of the same company, have recently returned from a five weeks' trip to California, where, naturally, they carefully inspected the famous power transmission lines. Mr. Rankine expressed himself as greatly pleased with what he had seen in the far West and that the power transmission lines were very good. One transmission is about 160 miles, but is to be carried 200 miles. The voltage at present is 60,000, but the pressure on the lines is not so great as on the Niagara-Buffalo line.

Considering the California transmission lines inspected, it is interesting to observe that were the Niagara transmission line stretched out 200 miles it would go beyond Cleveland, Ohio, on the one side and down close to Utica in the interior of New York State. In Pennsylvania even Pittsburgh in one direction and Lock Haven in another might be touched, while in Northern New York Watertown might feel the beneficial effects. California is the possessor of a dry atmosphere and there is a lack of sleet storms, but Niagara has the power and surrounding the Falls there is a marvelous market to which the transmission lines may some day carry the product of the mammoth generators to a greater extent than to-day.

TRADE NOTES.

THE CONSOLIDATED PUMP COMPANY, Toledo, Ohio, will at once commence the erection of a new plant at Sylome avenue and the L. E. & W. R. R., comprising two buildings, 80 x 250 and 60 x 100 feet, respectively, for the production of Wood Pumps, Door and Window Screens and other specialties. The new plant will have double the present capacity and is expected to be ready for occupancy within 90 days.

THE JEFFREY MFG. COMPANY of Columbus, Ohio, with New York City branch at 41 Dey street, are sending out an illustrated folder advertising the Jeffrey Mixing Machinery for mortar and concrete. This machine is made in a number of styles and sizes suitable for all kinds of building operations.

THE MICA INSULATOR COMPANY, 218 Water street, New York, manufacturers of Micanite Plates, Segments, Rings, Washers, Tubes, Troughs, Cloth, Paper, &c., have issued a notice calling attention to the effect that they are the owners of a large number of patents in the United States, Great Britain and Germany covering Micanite, and that they manufacture Electrical Insulators from Mica Sheets. Their rights under these patents have been almost universally recognized by the trade generally, among their customers being the largest manufacturers of electrical machinery in this country and in England. The company state that they have begun suit against the Union Mica Company in the United States Circuit Court for infringement of their United States patents. The officers of the Mica Insulator Company are: Eugene Munsell, president; Franklin Brooks, vice-president, and Lewis W. Kingsley, treasurer. The company were awarded a gold medal for their exhibits at the Paris Exposition of 1900.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin has advanced $1\frac{1}{2}$ c. for spot; demand is slack.
Copper is without change of any kind.
Pig Lead is quiet and firm.
Spelter shows no change.
Antimony is unchanged.
Nickel continues firm and active.
Aluminum is active at former prices.
Tin Plates are quiet and without change.
Black Sheets are still in heavy demand; jobbers' prices are slightly lower.
Galvanized Sheets are active and strong.
Sheet Copper continues active and firm.
Sheet Zinc is without change and in moderate demand.
Southern Foundry Iron was advanced 50c. a ton.
Hardware business is good in all seasonable lines and prices are well maintained.
Plumbers' Supplies are moving in good volume; prices keep firm.
Wrought Iron Pipe continues in good demand and prices are firm.
Galvanized Range Boilers of 30, 35 and 40 gallons have been reduced 10 per cent. in price.
Plumbers' Brass Work remains firm in price, with a good demand.
Solder has been advanced 1 cent a pound.
Building Papers have stiffened in price slightly on brisk demand.
Wire Nail prices are somewhat irregular.
Cut Nails are in fair demand and firm in price.
Wire still moves in good volume at former prices.
White Lead is less active and prices fairly steady.
Linseed Oil is still in short supply, but prices are a shade easier.
Spirits Turpentine is firm and rather quiet.
Rosin is slightly higher in price.

METAL MARKET.

NEW YORK, November 22, 1901.

Pig Tin.—Since our last report a corner in spot Tin was inaugurated by large interests in this city. The plan, it is said, was formulated about a month ago. Spot Tin was kept here below London parity until about ten days ago, in order to prevent shipments from London and to enable shipments to be made from here to the Continent. In that way the stock and the greater part of the shipments which can come in now were concentrated in one hand. It is now in the power of the controlling factor to dictate prices for spot delivery. In consequence of this condition prices have been advanced nearly 2c. a pound for Shot and 1c. for November delivery. The market here has been quiet, the buyers taking only small lots for immediate consumption. Straits Pig in small lots is now quoted at $28\frac{1}{2}$ c. to $28\frac{3}{4}$ c. per lb.

Copper.—Nothing has developed during the week to change the situation. Lake is still held at former prices. Buying is on a conservative scale, and rumors regarding the cutting of prices are less frequent. Small lots of Lake Ingot are quoted by jobbers at $17\frac{1}{4}$ c. to $17\frac{1}{2}$ c. per lb., and Casting Copper at $16\frac{3}{4}$ c. to 17c. The price of 17c., set by the Waelark Wire Company last week, is not accepted as the market figure by the balance of the trade. It is said that this company for some time have been selling Copper Wire below the regular market rate, this being possible through their connection with the Verde mines in the matter of raw material. The market price, it is said, has for some time been below

$18\frac{3}{4}$ c. Daily reports of the cutting of Copper prices have been circulated at a time when it was thought they would have the desired effect upon the Copper share market. The fact is that prices have not changed. It is still a waiting game on both sides. The report of the production of the Copper mines in October, contrary to expectations, showed an increase of over 10 per cent. over September, and was the largest monthly production on record. The European statistics were also a surprise, showing a very small decrease in stocks. This, in the face of our small exports and the steady shipment of Copper to this country, is held as an indication that the European consumption is still on the decrease, and the outlook for the near future in Europe is held to be anything but bright.

Sheet Copper.—An active demand is reported for Sheet Copper, which about keeps pace with the production, leaving little or no accumulation of stocks at mills or in jobbers' hands. Prices remain quite firm on the basis of 21c. per lb. for Sheet Copper from store.

Pig Lead.—The market for this metal is entirely unchanged. Business is rather slow, but prices are firmly maintained. American Pig in small lots is quoted at $4.62\frac{1}{2}$ c. to $4\frac{3}{4}$ c. per lb. St. Louis advices report no variation in that market from the quiet and steady tendency which has been the ruling condition for some time.

Spelter.—In another column details are printed of the proposed consolidation of Zinc smelters. The publication of this matter has had no appreciable effect upon the market so far, however. Business is dull and prices show no change from those ruling at the date of our last report. Western brands in small lots are quoted at 4.55c. to 4.60c. per lb. St. Louis advices report that practically all the Zinc smelters are sold up to January 1, and prices are holding firm.

Antimony.—No change has taken place in this metal. Cookson's in small parcels is quoted at $10\frac{1}{2}$ c. to 11c. and Hallett's at $8\frac{1}{2}$ c. to 9c. per lb.

Nickel.—Is without change, prices continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—The demand for Aluminum continues active. Prices remain at 37c. per lb. for small lots of No. 1 Ingot, guaranteed 99 per cent. pure, and 35c. for 100-lb. lots.

Tin Plates.—Nothing that is new can be reported in connection with this market, except that deliveries from mills are coming in rather more freely, although hardly in sufficient volume as yet to satisfy the demands of consumers. The mills are still considerably behind in deliveries on their contracts, orders placed many months ago being still unfilled in many instances. New business is of a limited character, but the American Tin Plate Company are understood to have booked some good sized contracts for deliveries extending through the first quarter of the new year. The small trade in this vicinity is pretty active for the season, owing to the weather being favorable for outside work. Jobbers' prices continue largely nominal, but American Bessemer Coke Plates, 1C, 14 x 20, at New York or corresponding points, rule at about \$5.75 to \$6.25 per box.

Sheets.—The mills are beginning to catch up with back orders and shipments are being made with more promptitude. Nevertheless, deliveries are not yet adequate to the requirements of consumers. A scarcity still exists of certain kinds of Black Plates, for which a heavy demand is experienced by jobbers. Receipts from the mills are absorbed as quickly as they arrive. There is quite a heavy demand for Galvanized Sheets and the market is relatively stronger for this class of material than for Black Sheets. On the latter, jobbers' prices are about 10c. per 100 pounds lower, and No. 27 one-pass Cold Rolled Soft Steel Sheets are quoted in small lots at about

4.05c. to 4.10c. Galvanized Sheets rule at 65 per cent. to 67½ per cent. off the list.

Chicago advices are as follows: While progress is being made in the accumulation of Sheets in stock, the latter are not complete and receipts are often absorbed as fast as they arrive. Prices are without further decline. Some sellers continue to quote 3.50c., but these prices do not include all sizes. Many transactions are on the basis of 3.60c. to 3.75c. from store. Galvanized are firm at 65 and 10 to 70.

Old Metals.—A pretty good demand continues for Scrap Iron, but prices are without change. Scrap Brass and Copper are moving rather slowly at former prices. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb.	14¾c.
Light and Tinned Copper.....	per lb.	12¾c.
Heavy Brass.....	per lb.	9¼c.
Light Brass.....	per lb.	7½c.
Lead.....	per lb.	4 c.
Tea Lead.....	per lb.	3½c.
Zinc.....	per lb.	2¾c.
No. 1 Pewter.....	per lb.	17½c.
No. 2 Pewter.....	per lb.	8½c.
Tin Plate Scrap, per gross ton.....		\$6.50 to \$7.00
Wrought Iron Scrap, per gross ton.....		10.50 to 11.00
Heavy Cast Scrap, per gross ton.....		10.25 to 10.50
Stove Plate Scrap, per gross ton.....		7.25 to 7.50
Burnt Iron, per gross ton.....		5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—Trade is active, in fact, exceedingly active for the season. Stocks continue to shrink under the heavy demand, and prices are strong with an advancing tendency. The Southern furnace companies have marked up their prices 50c. per ton on all grades and Northern makers are strongly inclined to take similar action. We quote: No. 1, \$16 to \$17.50; No. 2 X, \$15.15 to \$15.75; No. 2 Plain, \$14.65 to \$15; Tennessee and Alabama brands, No. 1 Foundry, \$16; No. 2 Foundry, \$15.25; No. 1 Soft, \$16; No. 2 Soft, \$15.25; No. 3 Foundry, \$14.75; No. 4 Foundry, \$14.25.

CHICAGO.—Trade in Pig Iron has been largely checked for the moment by the rise of 50c. in the price of Southern products, which took effect last week. For several days prior to the advance a number of orders for 500 to 2000 tons were entered, mainly for shipment during the first half of 1902. Some of the smaller purchasers say they will wait until after January 1 before buying any more iron. The position of the furnaces seems to be remarkably strong. Furnace men are not generally seeking trade and their output for the first half of the year is said to be well engaged. The Coke situation continues embarrassing for both furnaces and foundries. There is scarcely any of the better grades of Iron in the market. Prices, as corrected, are as follows:

Lake Superior Charcoal.....	\$17.00 to \$18.00
Local Coke Foundry, No. 1.....	15.50 to 16.00
Local Coke Foundry, No. 2.....	15.00 to 15.50
Local Coke Foundry, No. 3.....	14.50 to 15.00
Local Scotch, No. 1.....	15.50 to 16.00
Ohio Strong Softeners, No. 1.....	17.25 to 17.50
Southern Silvery, according to Silicon.....	15.90 to 16.40
Southern Coke, No. 1.....	15.40 to 15.90
Southern Coke, No. 2.....	14.90 to 15.40
Southern Coke, No. 3.....	14.40 to 14.90
Southern Coke, No. 1 Soft.....	15.40 to 15.90
Southern Coke, No. 2 Soft.....	14.90 to 15.40

PHILADELPHIA.—The market for Pig Iron has been remarkably strong during the week and prices are easily 25c. per ton better, and in some cases more than that. The demand has been very heavy and many large consumers have covered their requirements for the first quarter, and in some cases for the entire half of the coming year. All grades have been freely taken and Foundry Irons have been especially active, so much so that for this year's deliveries about everything that can be picked up is already engaged. Prices are strong at about the following figures for Philadelphia and nearby delivery, and about 25c. less for deliveries within a radius of 100 miles South or West: No. 1 X Foundry, \$15.75 to \$16; No. 2 X Foundry, \$15.50 to \$15.75, and No. 2 Plain, \$15 to \$15.25.

PITTSBURGH.—Foundry Iron is in active demand and prices are very strong. We quote No. 1 Foundry Iron at \$15.75 to \$16 and No. 2 at \$15.25 to \$15.50, Pittsburgh. We note a sale of 1000 tons of No. 2 Foundry Iron for shipment during the next four months at prices equal to about \$15.15, Pittsburgh.

CINCINNATI.—There has been but one move of importance in the Pig Iron market the past week, and that was the advancing of all grades of Southern Iron 50c. per ton. In the present condition of the trade there is no question in regard to buyers paying the advance without much objection, and it is considered a very conservative move by most sellers. Some few furnaces had been asking higher prices for a week prior to the raise of last Friday, and they especially are pleased with the move. All that has been said in recent letters regarding general conditions can be reaffirmed to-day. With the exception of the scarcity of cars there is very little to complain of; buying has been moderately fair and there is a pressing demand for Iron for quick shipment. We quote f.o.b. Cincinnati:

Southern Coke, No. 1.....	to \$15.00
Southern Coke, No. 2.....	to 14.25
Southern Coke, No. 3.....	to 13.75
Southern Coke, No. 4.....	to 13.25
Southern Coke, No. 1 Soft.....	to 15.00
Southern Coke, No. 2 Soft.....	to 14.25
Southern Coke, Gray Forged.....	to 13.25
Southern Coke, Mottled.....	to 13.25
Ohio Silvery, No. 1.....	\$15.35 to 15.85
Ohio Silvery, No. 2.....	14.85 to 15.35
Lake Superior Coke, No. 1.....	15.35 to 15.85
Lake Superior Coke, No. 2.....	14.85 to 15.35
Lake Superior Coke, No. 3.....	14.35 to 14.85

ST. LOUIS.—The advance announced by the furnaces last week may have momentarily checked buying, but the same strong and steady demand ruling before the change is now apparent in the Pig Iron market. A noteworthy point is the marked substantial quality of the buyers, no speculative element being found in the market. Some transactions in special grades are reported at an advance of 50c. over the new figures just quoted. Some furnaces have requested their agents to take no more business for delivery this side of January 1. We quote as follows for cash, f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$15.50 to \$15.75
Southern, No. 2 Foundry.....	14.75 to 15.00
Southern, No. 3 Foundry.....	14.25 to 14.50
Southern, No. 4 Foundry.....	13.75 to 14.00
No. 1 Soft.....	15.25 to 15.50
No. 2 Soft.....	14.75 to 15.25

CHICAGO REPORT.

Scrap Iron and Steel.—A feeling of uncertainty is quite noticeable among dealers. It is reported the Eastern Bar Association have formed a central purchasing agency for the purpose of buying what Scrap is needed by the different mills represented in the Association. It is stated that each mill will report their requirements 30 days in advance and in this way prevent prices being bid up. On the other hand, the Old Material dealers held a meeting in Cincinnati last week and adjourned to meet in New York on the 21st, and some interesting developments are looked for before the week is out. In view of the situation, as above outlined, the market is naturally quiet and prices are unchanged. We quote dealers' buying prices in carload lots, Chicago delivery, as follows:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast.....	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	to 8.00
Burnt Iron and Grate Bars.....	5.50 to 6.00
Sheet Iron and Hoops.....	6.00 to 7.00
Plow Steel.....	to 10.00
Breaking Stock.....	9.00 to 10.00
No. 2, such as Shovels, Hoes, &c.....	to 7.00
Old Boilers—whole (Iron).....	6.00 to 7.00
Old Boilers (Iron) cut in single Sheets and Rings.....	9.00 to 10.00
Old Gas Pipe and Boiler Tubes.....	10.50 to 11.50
Cast Borings.....	4.50 to 5.00

Horseshoes.....	to 13.00

Old Metals.—There is practically no demand for Copper and Brass, and while prices are not quotably lower, they are a trifle softer. Dealers quote buying prices on small lots as follows:

	Per lb.
Copper Wire and Heavy.....	14¾c.
Copper Bottoms.....	13¾c.
Copper Clips.....	14¼c.
Red Brass.....	13¾c.
Yellow Brass.....	9¾c.
Red Brass Borings.....	11½c.
Yellow Brass Borings.....	8½c.
Light Brass.....	7½c.
Pipe Lead.....	4 c.
Tea Lead.....	3¾c.
Zinc.....	2.80c.
Tin Foil.....	20 c.
Pewter, No. 1.....	17 c.
Pewter, No. 2.....	14 c.

Old Rubber.—Not much is doing in this department. Quite a surplus has developed in Rubber Shoes, and they are quoted ¼c. lower than last week. Dealers expect a further shading in the price of Rubber Shoes before the week is out:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7½c.
Rubber Car Springs.....	5½c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	7¼c.
Black Rubber.....	4¼c.
White Rubber.....	8½c.

Rags.—No change to note. Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at 75c. to 85c. per 100 lbs. in any quantity.

Anthracite Coal.—The demand is heavy, and no relief is in sight so far as the shortage of cars is concerned. The schedule for carload lots is as follows:

	Grate.	Egg and Stove.
Chicago	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

THE HARDWARE TRADE.

Reports received from the various classes of trade indicate a satisfactory condition of things and a very general activity. With the merchants it is a season when business is naturally of large volume and makes exacting demands upon those in charge. The approach of Thanksgiving, which is a precursor of the holidays, is accompanied by increased attention to preparations for Christmas and New Year trade, of which many merchants are making more of late than heretofore. In this they are encouraged by the existing prosperity, which puts the people generally into an exceptionally good position to purchase articles of the better grade or of luxury. On this account the indications are that business of this character with the increased attention given to it by hardware merchants will be unusually large. There is thus naturally a good deal of buying for the holiday trade in connection with the activity in winter goods generally. Among the increasing number of houses who buy well in advance of the season such lines as poultry netting, lawn mowers, steel goods, wire cloth, &c., are receiving especial attention, and the volume of business thus doing is heavy. There still continues to be a good deal of difficulty in getting certain classes of goods as fast as wanted, but the supply is catching up with the demand, and there is a prospect in some lines in which the manufacturers have been badly behind their orders that the trade will soon have little reason for complaint. There are, however, many who believe that in a good many lines there will next season be more or less scarcity if trade attains the volume anticipated. The general conditions throughout the country are most satisfactory.

NOTES ON PRICES.

Wrought Iron Pipe.—The demand for Wrought Iron Pipe has been steady and in good volume this week. The mills are getting abreast of their orders and there is less scarcity to be noticed than has been reported since the labor troubles at the mills began. Prices are beginning to show a slight decline with the jobbing trade, but mill prices remain stationary. It seems to be a settled conviction on the part of the jobbers that there will be no change in manufacturers' prices. The prospects are for a good, steady business until late in the spring of next year, and it is said that the work now in course of construction, together with that already projected, will consume the entire output of all the various mills now in actual operation. The mills of the National Tube Company are being operated to their fullest capacity, and it is said that this condition of affairs is likely to prevail for the next three months.

Galvanized Range Boilers.—The Range Boiler Association, at a meeting in New York City on November 19, reduced the price of the 30, 35 and 40 gallon Boilers

10 per cent. This reduction was brought about by competition outside of the association. It seems that the manufacturers outside of the association do not make a full line of different sizes of the Boilers, their entire energy being concentrated on the production of the three sizes upon which the prices have been changed. According to a statement made by a prominent member of the association, this move on the part of the association will practically put the outsiders out of business, and he further says that the price of the steel sheets from which the Boilers are made will not allow the outsiders to make up their goods and market them at these prices with any kind of profit to themselves.

Plumbers' Brass Work.—A meeting of the Brass Association will take place in Washington, D. C., the second week in December, when it is expected that the present prices will be reaffirmed. There seems to be no change whatever in the market conditions. Considerable effort is being made on the part of the various committees in the association to get the outside manufacturers into the organization. The association, it is said, is gaining in membership, and none of the older members have left it. Two of the largest manufacturers who are outside of the association are thoroughly in accord with it in regard to prices and terms.

Solder.—In consequence of the sharp advance in Pig Tin, the manufacturers of Solder have advanced prices about 1-cent a pound. Half and Half, guaranteed, is now quoted in a retail way at 18 to 18½ cents per pound and No. 1 at 15 to 17 cents.

Lawn Mowers.—The indications are for a satisfactory season in Lawn Mowers, with a good volume of business at reasonably remunerative prices. The trade apparently did not carry over a great many goods from last season, and the jobbers and larger retailers are showing a disposition to buy in somewhat more than the usual quantities. There continues to be a large demand for the cheapest grade of Mowers, which are, as a rule, sold at very close prices, leaving the manufacturers only a narrow margin of profit. These goods are necessarily of an inferior quality and serve their purpose for only a comparatively short time. While dealers continue to handle them in large quantities, there is said to be something of a tendency toward better goods, as the trade are becoming more critical and recognize the better value of the higher grades. The prices of this class of Mowers are slightly higher than last season, owing to the higher price of Iron and advances which have taken place in labor. There were, however, early in the season, a good many orders taken at about the same prices as last year, but there have been subsequent advances of 10 or 15 cents. Competition between the manufacturers is keen, which keeps prices down to a close figure.

Building Paper.—There is some stiffening in prices on this class of goods, a complaint being that it is difficult to get deliveries from the manufacturers on account of the brisk demand, while the congested state of the railroads, owing to a shortage of cars, further complicates matters. In car lots Rosin Sized Sheathing is being offered at \$25 to \$28 per ton, some quoting as high as \$30 and \$35 in smaller lots. In Tarred Roofing, single-ply, a fair price at manufacturing points is \$25 per ton; two-ply, per roll, 40 cents; three-ply, per roll, 60 cents; no freight allowance. Slaters' Tarred Felt is quoted at \$27 per ton in car lots, with an advance of 5 per cent. on smaller purchases.

Gasoline Fire Pots and Torches.—The Clayton & Lambert Mfg. Company, Detroit, Mich., manufacturers of Gasoline Fire Pots and Torches, issued new prices on their products under date of November 19, 1901.

Wire Nails.—There is a constant demand for Wire Nails, and orders are mainly for small lots, owing to the uncertainty felt by buyers regarding the future of the market. Prices are not uniform over the entire country, owing to competition, but regular prices are adhered to as closely as possible by the largest producers. In the New York market there is more or less irregularity in prices. Small lots from store are quoted at \$2.35 to \$2.40 per keg.

Cut Nails.—The market for Cut Nails continues firm.

and there is a fair demand considering the season. Small lots from store, New York, are quoted at \$2.20 to \$2.25 per keg.

Wire.—A fair amount of business is still being done in Plain Wire. Concessions in prices are said to be made for desirable orders and at competitive points. Small lots of Plain Wire in New York, however, are still quoted at 2.60 cents, and Galvanized at 3 cents.

White Lead.—There is a perceptible falling off in the demand for White Lead in Oil, incident to the restricting of outside work with the advance of the season. The market continues fairly steady for small lots of White Lead in Oil, which are quoted at 7 to 7¼ cents per pound.

Linseed Oil.—The supply of spot Oil is yet inadequate to fully supply the moderate demand. There is a difference of opinion among the trade regarding the future of the market. The opinion is expressed by some that after the first of the year prices will be much lower. On the other hand, it is said that 60 per cent. of the new Flaxseed crop has been purchased by crushers at the high prices which have been ruling, and that, in consequence, the crushers cannot afford to let the market fall off to any great extent. However, the market for spot Oil is easier. Raw Oil in small lots is quoted at 61 to 62 cents and Boiled Oil is 2 cents advance on Raw.

Spirits Turpentine.—The demand for Turpentine has been comparatively light during the week, the buying being confined to small lots. The market is firm at 38 to 39 cents per gallon for moderate sized quantities from store.

Freezers.—Prices of Ice Cream Freezers for 1902, just issued, are the same as those of last season, except in the Toy Freezers, which have been advanced slightly.

RAPID work is being done on the additions to plants and the building of the new mills by the Labelle Iron Works, at Steubenville, Ohio. The company recently increased their capital stock to \$3,000,000, and are putting in a new open hearth steel plant and blooming mill and are adding a tube mill. The Labelle Iron Works are not in any way identified with the Pope Tin Plate Company, now building a plant in Steubenville, but will probably sell material to that company.

The forty-fourth meeting of the American Society of Mechanical Engineers will be held in the society's parlors, 12 West Thirty-first street, New York, December 3 to 6, 1901. Secretary F. R. Hutton has issued a programme covering the subjects which will be discussed and the papers which will be read at this meeting.

Charles M. Schwab, president of the United States Steel Corporation, has agreed to donate \$50,000 toward the erection of a Y. M. C. A. building at Vandergrift, Pa., where the largest of the sheet plants of the American Sheet Steel Company is located.

At Pittsburgh, in the case of the Pittsburgh Supply Company against the Pittsburgh Meter Company, the Circuit Court found in favor of the plaintiff. This finding was reversed by the United States Circuit Court of Appeals, and the bill of the complainant was dismissed.

The men employed in the Monongahela Works of the American Tin Plate Company, on the South Side, Pittsburgh, are still annoyed a good deal by the strikers, and recently it was found necessary to ask for additional police protection for the men.

The Zeman Iron Works, at 1590 Broadway, Cleveland, Ohio, established in 1895 by M. Zeman, were incorporated on October 12. The name of the new company is the Zeman Iron Works Company. Mr. Zeman was elected president and will attend to the mechanical department. J. H. Nieding, formerly of the oil firm of

Schofield, Shurmer & Teagle, is secretary and treasurer. The new company have added considerable machinery to the former equipment of the works and expect to secure a larger part of the benefits resulting from Cleveland's building boom. They are manufacturers of wrought iron fences and of builders' iron and wire work generally.

**Sheet Metal
Pattern Drafting**

A course of instruction by mail for tinsmiths, coppersmiths, plumbers, sheet-iron workers, furnace workers, skylight makers and others that will enable a student to "strike out" working patterns for all kinds of sheet metal work. This is what a student says:

**His Course
More Than
Paid for Itself**

I am a tinsmith, and consider your course in Sheet Metal Pattern Drafting one of the best investments I ever made. Before I was half through I had realized from it more than the money paid for the whole course.

M. E. TOBIAS,
63 Fifteenth St.,
Wheeling, W. Va.

We teach by mail Mechanical, Steam, Electrical, Civil and Mining Engineering; Shop and Foundry Practice; Mechanical Drawing; Architecture; Plumbing; Sheet Metal Work; Telephony; Telegraphy; Chemistry; Ornamental Design; Lettering; Book-keeping; Stenography; Teaching; English Branches; Locomotive Running; Electrotherapeutics. When writing state subject in which interested.

taught by mail.

And 60 other industries employing 1,500 hands. Correspondence solicited. Address

L. A. SMITH, Sec'y.

TINSMITHS' HELPER AND PATTERN BOOK.

With Useful Rules, Diagrams and Tables. By H. K. Vosburgh.
Revised Edition, 120 Pages, 53 Figures, Size $4\frac{1}{2} \times 6\frac{3}{4}$ Inches.
Cloth Bound. Price, \$1.00.

We present a new and improved edition of this useful book, believing it to be one of the most important assistants to tinner and other mechanics that is published. The diagrams and patterns are now illustrated by means of new engravings, greatly improving the appearance of the book. The tables, rules and recipes have been carefully revised, these, with important additional tables, being printed from new type.

This edition is printed on fine paper, and bound durably in cloth, in a convenient pocket size.

The Tinsmiths' Helper is not intended to be a comprehensive treatise on sheet metal pattern cutting, which field is covered only by "The New Metal Worker Pattern Book," but it contains a collection of patterns of the most common occurrence, described in the plainest way. It meets the requirement of a simple hand-book for young tinner, and will be an invaluable aid to all sheet metal workers for the compilation of tables and rules alone. A list of the contents is given below.

DIAGRAMS AND PATTERNS.

A UNIVERSAL REMEDY FOR LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 800 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails. In 5, 10 and 15 lb. Pails.

Special Discount to Jobbers and Large Buyers.

ART In Metal Ceilings. GOTHIC STYLE.

One of the noblest styles of architecture and design is that known as Gothic.

The round arch style originated in France, the pointed arch being a later development.

From France, Gothic was introduced in England and Germany. It became extremely popular for churches, and is, perhaps, the leading one of the accepted styles for that purpose.

For the interior decoration of churches our Gothic design is particularly appropriate. The background is stippled, with stucco effect. The ornamentation is elegant in its simplicity and thoroughly in harmony with the characteristics of this historic style.

The New
Metal Worker
Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting
as applied to all branches
of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection of 218 problems and an elaborate explanation of the principles of pattern cutting, including Triangulation.

It embodies the problems of the former Metal Worker Pattern Book, all of which have been revised, and many of which have been entirely rewritten and solved by more approved methods. To these have been added 75 new problems and much other new material and explanatory matter, making this work a model of completeness in every respect.

ARRANGEMENT.

In point of arrangement the new work far surpasses the former one in that the problems are classified under three different heads, and simply indexed, and also that by means of a table of contents any required department of the work can be easily found.

CONTENTS.

While Chapter VI, comprising the greater part of the work, is devoted to the solution of problems, the five preceding chapters thoroughly explain the principles of pattern cutting, and place the student in possession of the preliminary information necessary to a thorough understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tanners, Cornice Makers and Sheet Metal Workers should be provided with a copy of

The New Metal Worker Pattern Book.

Price \$5, post or expressage paid.

THE ELECTRIC CITY GUTTER FORMER.

The Electric City Gutter Former can be bought for 50 per cent. less than other machines intended for the same purpose. This machine will do everything that can be accomplished by any other gutter former. No other machine can do better work. No other machine can do quicker work. The principle of this machine is entirely different from any other. It is more practical. Both the bead and the gutter are formed in one continuous operation. You do not waste any time in hard work in getting the body of the gutter in proper shape. Every operation is mechanical. Each Length of gutter is formed exactly alike. No other machine is as practical in its operation. No other machine will give as much satisfaction. The low price is very attractive. The machine will perfectly demonstrate our claims. Ask us about it. We gladly furnish information and price on request.

THE DOUBLE TRUSS CORNICE BRAKE CO., - 1453 Niagara St., BUFFALO, N. Y.

Our Improved Double Truss Cornice Brake is the most practical machine of its kind in the market. Let us send you a description of its merits. Our "latest" has a double edge on front leaf for making fine members and corrugations.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No 12 gauge, cut wire or bar-steel 1/2 inch thick, cut off and mitre angle iron 1/2 inch thick, and do it perfectly.

PRICE, - - \$35.00.

THE ART OF SELLING.

By F. B. GODDARD.

12mo. Flexible Cloth, 50 Cents.

In this book the author lets the reader into the secrets of the accomplished and successful salesman. illustrates his tact and finesse, and tells how he masters men; but beyond this, the work embraces much information which will be instructive and useful to all classes of business men. Besides suggestions to buyers, it contains chapters on "Changes in Business Conditions and Methods," "Salesmen's Compensation," "Retail Merchants and Salesmen," "Saleswomen," "How to Read Character," with a collection of clearly and tersely put important Legal Principles and Decisions Governing Sales. Sent, post-paid, upon receipt of price, by

DAVID WILLIAMS CO., Publishers and Booksellers, 232 William St., New York.

For Cutting Apart Stove Pipe Easily.

Niagara Double Cutting Shears are made in the most durable manner. The center blade is of solid tool steel, and the outer jaw is laid with tool steel. Both handles are drop-forged of wrought iron.

The Double Cutting Shears were designed especially for cutting apart cylinders of sheet metal. They are also very useful for cutting holes in sheets, cutting off the bottoms of cans, pails, etc., and a variety of other work. The center blade is pointed so as to be readily inserted in the sheet at any point to start the cut. A narrow strip of metal is cut out, and both edges are perfectly smooth.

CURVED MOLDING MACHINES

for making every style of sheet metal curved moldings quickly, cheaply and accurately. The hammer gives a perpendicular blow entirely preventing the drawing or twisting of the material while being formed.

GLOBE CORNICE BRAKE.

Brake with "Beader" and "Gutter Former" Attached.

With which to form Sheet Metal into Cornice Moldings, Ridge Caps, Skylight Bars; and with Beader and Gutter Former attached to Brake (price of which is extra) Bead and Form Gutters. Cornice manufacturers' Steel Straight Edges, 30-inch to 10-foot lengths.

Cornice Moldings, true and straight, are formed with ease and speed on the above illustrated 8-foot Cornice Brake, which brake is made of cast and wrought iron and steel, many of which have stood the test of twenty-seven years and more, and are good for several years to come.

High Grade Cornice Brakes—try them and save your strength, time and money.

Excelsior Point No. 1.—Eclipse Center Lift Covers.

These are found only upon ranges of our manufacture. They are lifted by a special lifter which fits into a little button in the center of the cover. The lifter hole is always before you. Any weight is lightest if lifted from the middle. They have no corners and therefore do not crack, as the common covers do. Eclipse covers are more convenient and more durable than the common cover, and yet they cost nothing extra. Free with all Excelsior Ranges.

**CRAWFORD
RANGES.**

Finest Factory in this Line in the World.

READ OUR OFFERINGS.

**Special Advantages Over All Other
Heaters.**

OUR HEATERS are only 4 ft. 3 in. high, giving excellent elevation for Hot Air Pipes.

OUR HEATERS ARE ALL CAST IRON, no repairing of sheet iron drums necessary every few years.

OUR MANIFOLD TUBES are steel, $\frac{1}{8}$ inch thick, and will wear for a lifetime.

OUR HEATERS are supplied with the most modern grates, perfect dumping and shaking. Each bar can be separately replaced.

OUR HEATERS are so arranged that they can be perfectly cleaned by any one, and in a few moments.

Equally Efficient with Hard or Soft Coal.

Our Heaters save the heat others waste up the chimney and send it through the house, therefore reduce coal bills.

Sunshine Stove Shop

To the Stove Trade Everywhere:

Greeting. This bit of publicity is to keep you in mind of Sunshine Stoves.

MYSTIC SUNSHINE.

We want every stove dealer to have our new 1901 catalogue. It is published in four sections===Ranges and Cooking Goods, Portable Heating Goods, Furnaces and Steam and Hot Water Heaters. Send for the parts in which you are interested.

The little engravings hereon represent two successful new things from the Sunshine Stove Shop this season. The Mystic Sunshine Range has broken all records for quick popularity. We sell this range to but one dealer in a locality.

We dare not urge the Daisy Sunshine too much===they go as fast as we can mount them. There will be lots of stoves sold yet before Easter. We got ready in time and are shipping on receipt of orders.

Don't mistake the name "Sunshine," the trade name that guarantees perfection in stoves, the name one always thinks of first in connection with stoves. We mean to keep record of the orders that this ad. brings and will send a valuable perpetual calendar to dealers who will simply write the words "Chalk Talk" on orders sent to us before December 21st.

DAISY SUNSHINE.

Model Steel Range

For Hard Coal, Soft Coal or Wood.

They are **Models** of all the good things, useful and beautiful, that can be embodied in a modern range. Their popularity, on account of their many good points, has led many imitators to copy them as near as they dare, but as the oven doors, dampers, fire-box and other features are covered by patents, the imitations are still behind in the race, so far as construction and operation are concerned, and we feel confident that a comparison will result in a most favorable impression as to our claim that they are **Models of Beauty** and just the one range above all others that it will pay the dealer to handle. The large and constantly growing trade we enjoy on the **Model Steel Range** has been built up purely on its merits and not through a lot of extravagant "fake" advertising.

Write for prices and discounts.

THE STANTON HEATER CO.,
Martin's Ferry, Ohio.

See Our Advertisement Next Week

NOBODY except the DIGHTON FURNACE CO. does now or ever did make a range that ALL of FIVE SIDES of the oven are heated flue surfaces. Since we originated the "HOME WINTHROP" construction, others have put double plates, asbestos paper, and various other contrivances to endeavor to protect ALL of the FIVE SIDES and economize in fuel consumption, but in not one single instance have any of these changes approached the results secured with the "HOME WINTHROP."

We not only get a larger working capacity in a smaller body than any old type of construction, we arrange every atom of surface to do its full proportion of business, and at the same time, assist and protect its connecting parts—no waste surface, no unnecessary parts.

	No. 7 x 18 or 8 x 18.	No. 8 x 20 or 9 x 20.
Fire Box Measures.....	15 1/8 x 7 3/8 x 7 Inches.	17 1/8 x 7 3/8 x 7 1/2 Inches.
Ash Pit "	16 x 15 1/2 x 4 "	17 3/8 x 18 x 4 1/2 "
Water Front "	17 x 7 "	19 x 7 3/8 "
Perfectly Square Oven.....	18 x 18 x 11 1/2 "	20 x 20 x 12 1/2 "

and when you read these measurements, just remember they are ALL in the body of a range that sells from \$5.00 to \$8.00 less than any other range having anywhere near the same vital measurements.

Burn Hard or Soft Coal, or Coke. Large Doors.

Some Ripe Experience

Has come to us through watching the doings of dealers throughout the United States.

We find that the dealer who sells cheap furnaces not only loses ground in the furnace business but also has a falling off in his other lines.

On the other hand, we can say that the man who sells a good furnace and charges enough to do a good job will, in a few years, be the leading furnace man in his town and at the same time build up his other business.

The *American Furnace* is made for the better class of trade; is durable, clean and economical in fuel.

PHILADELPHIA.

A Tea-Kettle Boils Quicker on my Chimney than on my Stove.

A fire in a red glow represents 1200 degrees of heat, a draft through this carries the heat out of the chimney unless intercepted by a cross tube **Rochester Radiator**, when nearly all this waste heat is conveyed into the room by the rapid circulation of air through the tubes and saved. This appeals to common sense and is verified by the most thorough scientific test.

The **Rochester Radiator** is a satisfactory article to sell and one that affords the dealer a good profit.

NEW ERA RADIATOR

HOT FACTS—OF WHICH THIS IS No. 1.

Nature has certain laws. One is that heat rises—another that rapid circulation must be had to heat a room evenly and healthfully.

There are radiators on the market that try to change these laws. But they can't do it. The New Era Radiator conforms to them and extracts the largest amount of heat from a given quantity of fuel. Its principles are right, its construction is scientific and accurate, and it sells at a price that is inducing to every economical housekeeper.

There is money waiting for every dealer who sells the New Era, and we can prove it.

RATCHET STOCK**

Is an indispensable tool for conveniently threading iron pipe in ditches, under floors in corners, over head, etc. With this tool threads can be cut without removing whole lengths of pipe. This tool is provided with a strong vise which securely grips the pipe and by means of the leading thread the die is forced on pipe and the thread is cut. It is made of malleable iron and steel, and while light in weight, making it convenient to carry, is very strong and rigid. The advantages of this tool make it absolutely indispensable to Plumbers, Steam and Gas Pipe Fitters, Gas and Water Companies, Machinists, etc. It takes standard size dies, which are extra if furnished.

No. 1 threads $\frac{3}{4}$ to 1 in. pipe takes 2 or $2\frac{1}{2}$ in. die, \$10.00.No. 2 threads 1 to 2 in. pipe takes $2\frac{1}{2}$, 3 and 4 in. die, \$17.00

Index to Reading Matter.....Page 51

Manufacture of Black Plate to Be Revolutionized.

We are enabled to make the authoritative announcement that the American Tin Plate Company are about to make a radical departure in the manufacture of black plate. They propose, briefly, to revolutionize the method of producing black plate, which will greatly cheapen the cost of the production of tin plate. The process which is to be introduced is one developed by the company and has no reference whatever to any new method which has been brought out by other parties. The construction of a plant on these new lines will be started at once, but its location, for special reasons, is not disclosed. That will, of course, be known in the near future. The new method is not an experiment, as satisfactory tests have shown that the machinery devised will do from two-thirds to three-fourths of the work which is now done by hand, and the output per mill will be increased to three or four times the possible output under the present system.

Automatic machinery has replaced skilled labor in almost every other line of iron and steel production, greatly reducing the number of men employed and the cost of labor per ton of product. In the manufacture of tin plates the introduction of labor saving machinery has been a most difficult problem, as many obstacles had to be overcome, but this has been accomplished by the American Tin Plate Company, and as great progress in manufacture in this line is promised with the construction of the new plant as has been shown by the developments in any other line.

Several years possibly may be required to build and equip a sufficient number of mills on the new plan to care for the full requirements of the trade, but the benefit of cheaper production will be felt from the time the first plant is constructed and in operation. Eventually the large business now going abroad for tin plates to be manufactured into goods for export, and on which a rebate of 99 per cent. of the tariff duty is refunded to the exporter, will be retained in this country. This, of course, leads to the natural expectation that an export trade will be established in due course of time.

A Good Stove Trade.

The season has reached a point when the manufacturers of stoves throughout the country can form a correct estimate as to how their sales for this year will com-

pare with those of previous years. From all sections alike come reports that lead to the conclusion that this has been a good year for the sale of stoves, and that the volume of business has been in excess of that of several immediately preceding years. In the West there is less hesitation on the part of manufacturing houses in stating frankly that their business for the year has already shown an increase. In the East, under the influence of conservatism, the manufacturers are more reluctant to admit that the number of stoves shipped exceeds that of other years, and has probably surpassed their expectations. However, it is not difficult to arrive at this conclusion in view of the information received from various sources. On this satisfactory feature of the trade the manufacturers and the dealers are to be congratulated.

Throughout the year there has been the usual strife between the buyer and seller in regard to prices. There has been some complaint on the part of the manufacturers that the prices which have prevailed have not been altogether satisfactory, and it is the opinion of some that they have not been as profitable as those of last year. The fact that prices have been irregular in some sections has caused the dealers to buy from hand to mouth. It is probable that the stocks in the hands of the dealers, owing to this manner of conducting the business this year, are not large. The natural inference from the conditions referred to is that the stove business generally may be regarded as in a very healthy and satisfactory condition. It is probable that the year's business will close so as to leave all concerned in an advantageous position for taking up the business of next year, when it opens. The winter and early spring months afford ample opportunity for the preparation of new goods and new plans for putting them on the market, and the period when trade is dull is usually characterized by marked activity in planning for the next season. If the dull months, which are near at hand, are utilized by the manufacturers for discussing questions of mutual interest in a broad manner with a view to eliminating the unprofitable and annoying features of the trade, the time will be well spent. The opportunity is certainly worthy of an effort on the part of all who are identified with this branch of the trade.

Business Checked by Shortage of Cars.

Nearly every branch of trade is more or less seriously hampered at the present time by reason of the continued shortage of cars. The situation is particularly embarrassing to the manufacturers of iron and steel. The furnaces are hungry for lack of coke, owing to the impossibility of obtaining sufficient cars to transport the fuel from the ovens, and many have been forced to bank down in consequence. This involves a curtailment of the production of pig iron, and a consequent deficiency of raw material in the steel and finishing mills. All classes of iron and steel manufactures are more or less affected, and the inconvenience caused to consumers is becoming felt on all sides. Considerable building is like-

ly to be interfered with by the lack of structural steel, and every industry that uses iron or steel will feel the pinch to some extent. Nor is the iron industry the only one that is suffering from the deficiency of transportation facilities. All business interests are sharing in the inconvenience caused by the shortage of rolling stock. The manufacturer cannot get his raw materials, the merchant experiences exasperating delays in the shipment of goods, and the consumer grumbles because he cannot at once secure the commodities he needs, while all unite in anathematizing the railroad companies for not providing adequate freight transportation. However, the railroad companies are not wholly, or indeed largely, blamable, for the orders for freight cars and locomotives placed during the past year have been on an unusually liberal scale, and there is every evidence that the companies have taken all reasonable steps to meet their obligations to the public in this respect. The explanation of the present difficulty lies in the abnormally large volume of current business. The enormous traffic in all kinds of merchandise has fairly swamped the existing railroad facilities, and nothing but a radical increase of terminal facilities and other appliances for handling traffic would meet the exigencies of the case. This increase, however, cannot be provided at short notice. Meanwhile, no remedy for the present trouble being forthcoming, the only thing to do is to exercise patience.

Skyscrapers for London.

With American capitalists absorbing the surface and underground traffic of the British metropolis; American machinery, locomotives, rails, tools and other manufactures invading the British market; American concerns erecting great plants on British soil; American horses carrying off the prizes on the British turf, and American women filling the ranks of England's aristocracy, the "American invasion," of which so much is heard just now on the other side seems to be a very substantial fact. The latest phase of this invasion is a proposal to introduce into London that peculiarly American institution, the skyscraper. An Anglo-American syndicate are trying to get permission to erect a twenty-story business building in the heart of the British metropolis. The scheme meets with both opposition and encouragement from the English press. It is claimed, on the one hand, that a huge structure of this kind will be utterly out of harmony with its surroundings, that it will dwarf and obscure many of the handsome buildings located near the site which has been chosen by the promoters, and that it will in no way tend to the beautification of the city. The greatest city in the world has a low sky line. Most of the buildings are but a few stories in height, and the putting up of a huge skyscraper, it is contended, would be an eyesore which would not in any way compensate for the conveniences claimed for it. On the other hand, a section of the press claim that these high buildings provide just what is urgently required to meet the wants of the enormous population of London. The business section of the city is restricted in area, and for some time past a lack of adequate facilities for the expanding needs of trade has been found. The solution of the difficulty, it is believed, would be best presented by the erection of such high buildings as now exist in the leading American cities. Moreover, in adding to the business area and to the convenience of doing business, these tall buildings undoubtedly have the advantage of providing better light and ventilation than is possible in the older and lower structures. Whether the skyscraper in London would have the advantage of rising above the

fogs which are so undesirable a feature of that city it is impossible to say. If this advantage could be demonstrated, there is no doubt that all opposition to the erection of these lofty buildings would vanish. The successful introduction of the skyscraper into London would make a radical change in that city, and would no doubt be followed by its adoption in other of the large cities of the United Kingdom, and many of the Continental cities also. It is impossible to say that this development will add to the beauty of European cities, but the utility of the business skyscraper has been proved in our own case, and, in these days of keen commercial rivalry, everything that tends to the lubrication of the wheels of business is certain to appeal to the public at large on both continents.

The Contractors' and Manufacturers' Protective League of St. Louis, Mo., have taken action which is expected to prevent sympathetic strikes during the period of construction of the World's Fair buildings in that city. A letter has been sent by the league to the Building Trades Council of St. Louis and vicinity, stating that they are prepared to extend to those contractors whose work is stopped by reason of sympathetic strikes such active and financial support as may be necessary to complete such work with labor unaffiliated with the Building Trades Council. The officers of the league have notified the Building Trades Council that unless the sympathetic strikes now in operation in St. Louis, and others which are said to be pending, are called off, labor unaffiliated with the Building Trades Council will be procured locally or outside the city and used to complete the buildings. Letters have also been addressed to the various unions affiliated with the Building Trades Council, calling attention to this action of the league, and asking that serious attention be given to the same. The league assert that they are not directing a fight against any union, and that they would regret the necessity of importing labor, but that such action will be forced upon them unless the Building Trades Council see fit to act in accordance with the notice given to them.

The sailing of the oil carrying steamer "Cardium" from Port Arthur, Texas, with the first cargo of Beaumont oil for Europe, is an event of considerable importance to the oil producing interests of the Lone Star State. The shipment consisted of 60,000 barrels, and was made by the J. M. Guffey Petroleum Company, the owners of the great Lucas "gusher." It is hoped that this shipment is merely the pioneer of large exports of Texas oil to Europe. Late advices from Beaumont report a movement looking to the consolidation of many of the Spindle Top oil interests, which is expected to embrace nearly all the oil wells on the famous hill. The greatest difficulty now being experienced by the Texas oil men is to secure enough tank cars for the transportation of their product. Many hundreds of these cars are being constructed, and all that are turned out are put into immediate use.

Census bulletins of manufacturers have now been issued for twenty-four States and Territories. These statistics, which include, however, only four of what may be characterized manufacturing States, and those the smallest of the class—Connecticut, Rhode Island, New Hampshire and Delaware—show an increase in ten years of 62 per cent. in the capital invested, of 61 per cent. in the value of output, 37 per cent. in the number of wage earners, and 33 per cent. in the amount of wages paid. The comparative falling in wages indicated in the last item is accounted for by the fact that the statistics include the Southern States, where many women and children are employed at low wages in the new cotton mills. Otherwise the figures presented show a gratifying increase which is likely to be largely expanded when the statistics covering the larger manufacturing States are presented.

The Eastern Stove Trade.

The article in the last issue of *The Metal Worker* relating to the condition of the Eastern stove market has evidently attracted a good deal of attention in the trade. We have received a number of communications relating to it and commenting in different veins upon the position taken. From these letters the following extracts will be of interest:

THE NEW YORK CITY STOVE, RANGE AND FURNACE MANUFACTURERS' ASSOCIATION; ITS RISE AND DECLINE.

To the Editor: I read the article in the issue of November 23 entitled "The Eastern Stove Trade," and noted the reference made to the New York City Association that "there is no evidence of its life."

As one who was never absent from its meetings, always punctual and attentive to all its debates and deliverances, I feel that I am competent to write its history, and, in justice to many loyal members, warranted in doing so, that those unfamiliar with the cause of its decline may know why this once powerful and useful stove association, and which for a time, at least in the estimation of many, was the best in the country, lost so much of its influence and ceased to be the great pedestal of the wholesale stove trade of this vicinity.

It is not dead but in a state of suspended animation. Its influence is still felt. Its schedules of prices, the result of the hard work of the price committees, which included some of the best heads in the stove business, are still the guide of many of its members and some still maintain them in spite of the fact that association inaction is equivalent to a release of price obligations.

Its organization is as complete as it ever was, and it can be called into renewed activity at any time.

The credit of organizing the stove trade in this locality, as everybody knows, belongs to National Secretary Thomas J. Hogan, who came here to tackle the hardest proposition of his life and succeeded.

No matter what is or may be said of it, the association accomplished great good and perhaps saved from financial embarrassment more than one concern afterward found among its detractors or who libeled the members with the dealers by calling it a trust.

No worse condition ever existed in the trade anywhere in the country than existed in New York City in 1898, and ruin to some was inevitable but for the timely organization of the New York City association and the great work accomplished of re-establishing prices on a profitable basis.

Long sessions were frequently held, members came from long distances, the interest was intense, discussions earnest and practical, officers and committees worked hard, and from the slough of despond or the bottomless pit the wholesale stove trade of this locality was lifted to a plane of respectability and reasonable profit.

For fully 18 months, if not quite two years, the association flourished and the members worked in harmony and a high degree of loyalty.

That it was so successful is more the wonder than that it did not continue to grow stronger, when one considers how many conflicting elements had to be harmonized, how many sections were represented, how many thousands of stoves there were to equalize the price of and how much outside competition it was obliged to confront.

The rocks were not unknown to the more experienced and the danger of disruption not unforeseen. Legislation followed the lines of equality as near as it was possible to do so, that no member might intentionally be deprived of his due proportion of the local patronage to cause his withdrawal.

The elements of weakness that were born with the organization were only what nearly every trade association has to take into account, except that they were more numerous in the New York City body.

The agencies that worked for harm and gradually undermined its usefulness were those only that the wiser heads mistrusted would gradually sap its strength.

New York City, the great trade center, to which all roads lead, and accessible from everywhere, was apt to become an inviting market for some manufacturers whenever, through the association, stove prices had been raised to a profitable standard, although the same concerns might have left it severely alone when conditions were the reverse. Hence a conservative policy was followed to keep off fresh outside competition as long as possible and not augment the volume of unallied competition existing at the time the organization was formed.

There are always one or more prominent concerns who will not join their competitors in an association on the ground that it is against the policy or tradition of their house to do so. They sympathize with, rather than oppose, the movement for the betterment of conditions and promise co-operation as long as the association behaves itself and its members are not found cutting prices.

In every case of this kind trouble sooner or later may be looked for. The salesman for such a house becomes a self appointed detective. He goes gunning at once for evidence of price cutting by one or more of the association members, all of whom he is sure are in league against the house in which he is employed, and he is anxious to rescue his employers from the snares of bunco competitors.

Documentary evidence has first preference, but is impossible to find, and direct oral testimony is next sought for without success.

Failure to obtain proofs of guilt only whets his determination to convict somebody. That somebody is generally the one who has been his most bothersome competitor. At last a dealer is found who has purchased some goods from the suspected competitor, and the salesman is convinced that cutting the price won the order. He puts the dealer through the thirty-third degree, but finds his conduct most exasperating in not admitting that he bought lower and showing the bill. Nothing can be got out of him except a shrug of the shoulders and a slight wink of the left eye; but that is enough. He goes home and confides the information to the manager.

He saw no bill, but the dealer's actions are all he needed to be convinced that the order had been turned by price violation. The manager does not act on this, but the polson has been administered to his mind and doses are given with frequency without anything to serve as an antidote, as he does not attend the association meetings, confer with his competitors or use the association machinery to investigate the truth or falsity of any suspicious charges.

There is the merchant of superior dignity, who treats his competitors courteously, but declines to join with them in an association on the high ground of inexpediency. His prices are always higher than any of the others and above the association schedule, so that it would be hurtful to him to join. It is generally experienced that such merchants step down from their lofty perch and mingle with the common herd, even at the expense of some dignity and their high ideals, as their prices are found to be cut below association rates just enough to give rise to a suspicion that the schedules furnished them by the association were used for just that purpose.

There is the little fellow who really thinks it funny that the manufacturers should care a straw about him. He sells so few goods he should not be minded at all. Nobody will feel his presence in the market. He is but a very small toad in the puddle. Let these great big manufacturers go right ahead and perfect their organization, make prices what they should be and drop such small fry out of consideration altogether.

More respect is due to the other little fellow who says frankly that he will not join because he cannot get as much for his goods as A, B or C, and he would not pledge himself to not sell below a certain price because he might need the money so bad that he would have to.

There is the concern who never will say that they will not join, but hold out hope that they may come in later, and if they finally do join it generally develops that they have placed a great many blanket orders

covering certain customers' demands for a year or two ahead.

Inside of any association there are several members whose course of action or inaction tends to weaken its influence.

First, there is the member who does not attend the meetings and is always underselling until new prices are called to his attention.

Second, the member dull of comprehension, who is always misinterpreting the rules, though ever ready to do right when they are explained, and regrets that orders taken under a wrong version will have to stand, as he is under a contract to furnish the goods.

Third, the member whose clerks are always making mistakes, for which he is sorry, but will write customers withdrawing prices from that date.

Fourth, the member whose cut prices were for "a few old pattern goods" which he seems never to sell out.

Fifth, the member who is always selling under an old contract.

Every trade association operating under a so-called gentlemen's agreement is short lived so far as its vigor and usefulness are concerned. It may exist for years as an organization in skeleton form, but as a continuing potent force, and an organization whose rules, regulations, prices and terms are strictly enforced, uniformly observed, and whose members all strive for improvement and aim at perfection of the purposes for which it was formed, it fails.

In its very nature many of its parts commence at once to try and break the cohesion by surreptitiously doing what the association is organized to prevent—the selling of goods or making of terms below a legislated standard.

It is impossible to equalize the honor of men. One man will stand by his promise although his business and the heavens fall, or he will honorably resign. Another will violate the rules with audacity. Between these two there can be no compromise. Another will trim, dodge and quibble.

It is impossible to equalize the brains of men. A very dull man is apt to be suspicious of every statement or resolution that may be offered by a very shrewd man, and will always think that he sees some attempt to take an unfair advantage of him, while such is not at all the fact.

In an open market he does not complain, having no right to do so, but in a trade association he feels that his rights are being transgressed.

Again, there are scores of unequal goods, the age and style of patterns, equalization of which it is almost impossible to accomplish with satisfaction all around.

Another source of dissatisfaction exists in the fact that a small manufacturer may have but one size of an article to offer to a certain class of customers, while others have other sizes below it, and he insists upon a differential that will enable him to sell his large size at a price nearer that of the smaller, regardless of the difference in cost.

The first departure in allowing such differential brings requests from others for similar consideration on other lines.

Then there is the manufacturer whose jobber in another section comes to the newly protected field and undersells the maker, who is a member of the association, which causes irritation.

For reasons such as I have narrated, perhaps all of them, perhaps more, but less of a nature affecting the faith of the members than the disturbing element from without, the New York Association lost interest for its members.

There never was any breach or quarrel, never any stampede from it, or any spite prices quoted. No reaction of consequence has occurred since the former recommendations of the association as to prices were considered to be inoperative, simply because prices were based on reason, and lowered when the market required, and left no margin for serious cutting that would not do violence to the cutter's cost and remind him forcibly of 1898.

Prices during all the season have been fairly well maintained and generally the business has been con-

ducted on a plane of reason, respectability and reform as compared with some years in the not remote past.

For this result some thanks to the association wherein practices and policies and costs were threshed out so thoroughly and understandingly that everybody knows better what is the breaking strain of his prices than he did before it was brought into being. Yours truly,

EQUITY.

A MANUFACTURER'S CRITICISMS.

To the Editor: We have carefully read the article in your issue of 23d inst. There are several paragraphs which we do not fully understand.

We were not aware that, so far as manufacturers may have agreed upon prices and rules, exceptions had been made that governed to a greater extent than the agreement. Your research in this direction is certainly a revelation to us.

The independent action to which you refer has been only too pronounced. It seems hard for some minds to consent to unite in judgment with others even to secure good results.

As to prices and concessions, we are glad to be able to say that our company have universally followed out their long practice of adopting fair prices and using all dealers alike.

The "bad blood" and "restive under restraint" both require an explanation for us to know what is meant by them.

Some things called violations are only misunderstandings, and we have found that in most cases men are about as honorable to-day as ever, and quite as much so in stove manufacturing as in any other business.

What you call "paid secretary," so far as Eastern Pennsylvania manufacturers are concerned, is simply a weather bureau in charge of a statistical reporter.

In our mind there is no call for a magnificent leader so long as we have the efficient Executive Committee to look to for judgment and advice.

If it has to be the "survival of the fittest," we will risk our position along with the rest.

ANOTHER INTERESTING LETTER.

To the Editor: The Eastern Stove Association question does not seem to be one of wrong methods or ideas. For those in use have been used in other trades and proved successful.

The machinery inaugurated is all right, but the trouble is with the man or men who run the machine. Like the Spaniards, their guns were all right and of the approved type, but the men behind the guns were not right. It is so with the Stove Association. Their rules and regulations are correct. Their aims are right, honest and true, but the men themselves are not. So what can you expect?

No business man or association of business men can fool many people very long before he is found out and his finding out is what weakens the concern or the association. The flexible backbone seems to be the prevailing element among stove manufacturers. A chicken hearted fear to do business correctly and compel the other fellow in the association to either do the same or fight, and when the colored man in the wood pile shows his head, hit it and hit it hard, and if that cannot keep the colored man out of the wood pile, then load it with the proper kind of gunpowder and bust him up.

This may seem harsh, but if the honest man remains in the association his business leaves him, and he has the choice of either leaving the association or his business leaving him, and one large manufacturer of the New York City Association had to make that choice and decide just that condition, whereas if the colored man had been hit square between the eyes it would not have been so.

The man or set of men that have the backbone to do such work and carry the power to force it, may not be born—if he is we do not know him—yet he may exist and later come forward on the stage and show himself. But that something more than moral suasion must be used to keep associations not only together, but working to the profit of all and not to that of a few, is evident to every thinking stove manufacturer. The strong man was found in the steel industry, and in other industries; so

it is possible he may show up some day in the stove business.

Good times will not last forever, and the strong man will be needed then more than just now, so that it behooves the members who really care to keep their eyes open and ears to the ground that they may find him.

That it is better to run with machinery that does not turn out exactly the quality of goods you want than not run at all goes without question—but, say, don't it make you sick when you look at the fine quality of work others turn out with less cost and trouble? Can our associations reach the higher quality?

C. B. E.

THE PROFITABLE DISTRIBUTION OF GAS STOVES.

In order that gas stoves might be introduced quickly the gas companies adopted the method of selling these stoves at practically the same price that they paid for them, and, being large buyers, they have frequently been able to purchase gas stoves at lower prices than those at which the regular stove trade could buy them. A correspondent who has been identified with the gas stove trade for a number of years, and who is thoroughly familiar with all its usages, sends us the following letter:

"The article on the gas, gasoline and oil stove trade printed in *The Metal Worker* a short time since covers many points of great interest, particularly to the manufacturers of gas stoves. It must be understood that the gas companies have been the principal distributors of the output of the manufacturers, and to them is due the rapidity with which such goods have been brought into popular favor. It must not be forgotten, however, that, owing to the desire to secure the business of the gas companies, close, and I might say fierce, competition resulted among those manufacturers who desired to obtain it. The prices of gas stoves have been pounded down to such an extent that a fair return is not received for the labor, material and enterprise necessary to produce them. In some cases goods that may be said to have had their day are entered into competition with later and better productions. Yet on price old goods are winners. The fact is that enterprise in the production of new goods is in a measure stifled, and the consumer is unable to obtain that which progress could readily furnish—an economical, safe and efficient gas stove.

"Owing to the fierceness of the desire to sell their product conference among the makers of gas stoves, having in view the betterment of profit, is practically futile, at least in the East. An earnest and persistent effort to this end was tried a few years since, but it resulted in a reduced business for those whose desire to secure an adequate profit on their business led them to maintain an increase in the prices quoted on their goods. The temptation to sell large orders was too strong for some who attended the conferences, and they accepted orders at the old prices, to the disadvantage of those with whom they were supposed to co-operate.

"The business of making gas stoves should be both profitable and perpetual for many reasons. First, there is an increasing demand, and then the improvements in gas stove construction have followed one upon another very rapidly, and the active life of a gas stove, so far as its sale is concerned, is very brief. There are coal stoves for cooking and heating purposes that have held the market for 20 years, but this is not so with gas stoves. Probably four years would average the limit of the demand for the most popular goods. In consequence the gas stove business has not come up to the expectations of those who have entered it as a new field for business enterprise. It may be said, in fact, that this branch of trade has experienced more shadow than sunshine.

"Perhaps the greatest evil of all, however, is the consignment of goods. Very little has been said on this point, and, frankly stated, it is too sore a point for manufacturers to dwell upon. Happily for the trade, however, it has diminished somewhat during the past two years. In many instances, while the gas companies are large purchasers of gas stoves, nearly all the stock that they carry is on consignment, leaving the burden en-

tirely with the manufacturer. Naturally this could not be otherwise, when it is considered that the gas companies merely sold the stoves in order to increase their sale of gas, and not for the profit that could be made on them. In view of the fact that the manufacturers had to consign the goods and furnish the capital to carry them for the distributing branch of business, it is probable that if they had been more vigilant in taking care of their interests better prices could have been secured.

"There can be no doubt that the distribution of gas stoves through the regular business channels—the stove dealer and the hardware merchant—would result beneficially to the manufacturers. In some small cities this has been tried with success and advantage to all concerned. Doubtless, if this method was adopted by all, it would prove a success. At least it would awaken the interest of the dealer if the goods could be sold by him and on their merits. At any rate his interest would not be lessened, and it is probable that a higher grade of gas stoves would be more generally used. It is my opinion that the gas companies in the larger cities are not opposed to the natural distribution of gas stoves, through the medium of the hardware merchant and the stove dealer, now that the objective point has been reached of the rapid introduction of these stoves so as to create an increased demand for gas. It is possible that if it be shown to be desirable, and the manufacturers would present this view of the case to the gas companies through an organization, these companies could be influenced to pursue a course that would leave the distribution to the regular retail dealers. The gas companies in the city of Milwaukee at one time made free connections to their service pipes for all gas ranges sold by the dealers. The statement has been made that a percentage was also reserved for the regular dealers on all sales effected on gas goods, which had the effect of stimulating the regular dealers to enter more heartily into the work of increasing the scale of gas stoves, and thereby extending the demand for gas, which is the principal desire of the gas companies."

Cooking Exhibit and Range Sale.

Those who adopt special methods for increasing trade on any line will be interested in a plan which has been found successful by the enterprising house which has brought it to our attention.

The Holder-Athey Hardware Company of Bloomington, Ill., recently had a sale of steel ranges during the week of a cooking exhibit. A section of their show windows was devoted to the ranges, and in the next section were heating stoves. The week following the exhibit parallel horizontal cords were strung in front of the stoves next to the plate glass, and on the cords were hung cards, of which the accompanying cut is a repro-

Show Window Card.

duction, reduced in size. The cards were of heavy Manila stock, $7\frac{1}{4} \times 13\frac{3}{4}$ inches in size, printed in red ink. These were attached to the cords by wire fasteners near the upper corners. A much larger card, suspended in the window, explained that the other cards represented the number of ranges sold the previous week. The exhibit was advertised in the daily papers of the week previous, and during the exhibit a large streamer was hung across the front of the store. A range was in constant operation, biscuits were baked and served with coffee at little tables. During the week 37 ranges were sold, besides as many or more other stoves. The company have had these exhibits a number of times, but this one was the most successful. The company, however, consider their best advertisement the several hundred ranges used in their vicinity which had been purchased in their store.

The Tropic and Beacon Sunshine Furnaces.

"Healthful Heat" is the title of a neatly printed pamphlet which is being distributed by the Reading Stove Works of Reading, Pa. It is pointed out in the introductory pages that heat of the quality indicated may be obtained by the use of Sunshine furnaces, of which the company manufacture a variety adapted to cover all reasonable requirements. Special reference is made to the Tropic Sunshine and Beacon Sunshine as possessing large heating capacity, giving the dealer and consumer a maximum of service for a minimum of cost. The Tropic Sunshine, in its design and construction, is thoroughly up to date, and the furnace is built on advanced principles. The combustion chamber is large and effective, the radiator, made of either sheet or cast iron, is so arranged as to necessitate the heated gases traversing a long distance; the fire pot is heavy and the grate of the most modern type. In the construction of the heater the company state that their first consideration was to make it air tight and gas tight. All of the necessary joints are made with deep cups and sand sealed. All parts are made interchangeable so that repairs can be readily furnished.

The Beacon hot air furnace has been brought out in order to meet the demand for a cheaper heater than the one just referred to. This has been done by use of a new radiator, and a change in the upper part of the Tropic, the essential features being practically the same as those mentioned. It is made with a plain front only. The company state that it is not a light flimsy furnace, but a good heater for a small amount of money. In connection with the illustrations and descriptive particulars, are tables giving dimensions and capacities together with other data likely to prove of interest in this general connection.

The company have also issued a folder intended for display purposes showing some of their leading lines of ranges and heaters. Among the number may be mentioned the Othello, Colonial Sunshine and Mystic Sunshine ranges; the Golden Sunshine, Regal Sunshine, Brilliant Sunshine, and Bonnie Sunshine parlor stoves; the Sunshine Oak, the Sunshine Hot Blast, and the Daisy Sunshine. This folder is issued in a neat cover carrying an inscription to the effect that "The Sunshine Stove Shop is continually turning out something new; hence our exclusive agents are always in the lead." The company announce that their heating department is always ready to supply information relating to furnace heating or installing steam and hot water jobs.

Pioneer Stove Company.

The Pioneer Stove Company, Columbus, Ohio, are sending out a circular containing an announcement to the effect that they have succeeded the old and well-known firm of C. S. Reynolds & Co., stove manufacturers, and that all orders for future shipment with C. S. Reynolds & Co. will be filled carefully and promptly by them. "In addition to the present large line of stoves, ranges, heaters, repairs and supplies," they say, "we are adding new and desirable patterns, and have arranged to greatly increase our facilities for doing business, so that now we are able to offer you anything in the way of stoves. Our offices and warehouses are still located at the same places, and if you favor us with a call, you will find your old friends here to welcome you, or, we will be pleased to quote you low prices by mail." They also make the statement that they have a new line of Round Oaks and Hot Blast heaters, and give the names of their coal and wood cooking and heating stoves. The last page of the circular states that the business was established in 1826, and was incorporated in 1901 as the Pioneer Stove Company of Columbus, Ohio.

JEWETT & Co., with offices and foundries on Mississippi street, Buffalo, N. Y., are meeting with a gratifying demand for their goods and report a very satisfactory increase in the volume of their business. The foundry has been substantially in continuous operation since early in January, and the indications are that the plant will be kept fully occupied right up to the holidays.

A Fine Illuminating Display.

An interesting feature of down town St. Louis, and one which attracts the stranger and the resident alike, is the fine electrical effect produced by the 600 incandescent lights and 16 arc lights outside and inside of the building occupied by the Ringen Stove Company on Sixth street, between Locust and St. Charles streets. The company take great pride in the arrangement of their store and window display, and they are to be congratulated on the success of their efforts and the striking manner in which their ideas have been carried out. Their showroom is a thoroughly modern and fine one in its appointments, and is the largest in its line in the city. In fact, it is a question if a better one can be found anywhere else in this country. When the full power of illumination is turned on the building from sidewalk to roof is one mass of light of different colors, tastefully arranged, with the well-known "Quick Meal" title and the name "Ringen Stove Company" standing out boldly. It is an expensive method of advertising, but it wins the public eye and accomplishes its mission most satisfactorily.

ODD PLATES.

FRANK BALDWIN of New Castle, Pa., has been appointed general manager of the Pittsburgh Stove & Range Company, with headquarters at Pittsburgh.

W. H. COLEBROOK SONS & Co., Syracuse, N. Y., do not intend that the trade shall suffer from lack of information in reference to their Asbestos Furnace Cement and Stove Putty and a variety of other Stove Dealers' Supplies which they handle. The company's latest method of calling attention to their product is a card showing the fact of a supposed turkey sticking out from the top of a paper bag, with the inscription, "Don't Miss the Stuffing." The stuffing is a circular in reference to their goods.

THE MOUNT PENN STOVE COMPANY, Reading, Pa., are distributing to the trade a very neat spring tape measure, 36 inches in length. It is of vest pocket size and will be found a very convenient article for measurement in connection with Stoves, Heaters and Ranges, as well as other articles.

Novelty Coal Hod.

H. H. Franklin Mfg. Company, Syracuse, N. Y., have just put on the market the novelty coal hod, No. 3, here-

Novelty Coal Hod.

with illustrated. It is a fine metal casting, silver plated, polished and lacquered and particularly suitable for holiday trade. Its extreme height, including raised ball, is 2½ inches, the body of it being designed for holding toothpicks, pins, matches, cigar ashes, or any small trinkets. They are put up in individual boxes and sold to the trade by dozen or gross, and can be retailed at 25 cents each at a good profit.

WILLIAM L. DAVIS, president of the Davis & Wright Company of Keene, N. H., died from pneumonia at his residence on Dunbar street, on Monday, November 25, at the age of 78 years. He originally learned the trade of a blacksmith, but in 1865 he went into the Stove and Tinware business with Joseph Wells. This firm were suc-

ceeded by the Davis & Wright Company, of which he was the president. He celebrated his golden wedding on October 27, and is survived by a widow, one son and three daughters.

Washington Hardware Association.

The annual meeting of the Western Washington Hardware Association was held at Tacoma, Wash., on November 13. The most important action brought up was the matter of changing the name of the association and the enlarging of its scope. Owing to the fact that there is no Hardware association in Eastern Washington and that Hardware dealers in the eastern part of the State have shown a desire to come into the association, it was decided to change the name of the organization to the Washington Hardware Association and to invite all Hardware dealers in the State to join it.

The question of affiliation with the National Retail Hardware Dealers' Association was brought up during the meeting, but it was decided that for the present year all the endeavors of the members should be directed to the building up of the State organization, and that formal application for membership in the National Association should be made at the next annual meeting.

The following officers were elected to serve during the ensuing year:

Henry Mohr, Tacoma (re-elected), president.

F. M. Scheble, Wenatchee, vice-president.

D. G. O'Brien, Seattle, secretary.

C. W. J. Reckers, Seattle (re-elected), treasurer.

It was decided to admit traveling men representing hardware firms as honorary members of the association.

After the close of the session the members participated in a banquet given at the Hotel Tacoma. An orchestra was in attendance, and an interesting and enjoyable evening was spent.

The following members of the association were present: Henry Mohr, Tacoma; R. I. Morse, Whatcom; J. W. Campbell, Seattle; Charles Hood, Puyallup; C. D. Patch, Seattle; Mills & Cowles, Olympia; William Christensen, Ballard; J. F. Wellborn, Whatcom; Thomas Moran, Arlington; C. S. Enger, South Tacoma; F. M. Scheble, Wenatchee; A. Gehri, Tacoma; George L. A. Forck, Tacoma; W. M. Olive, Mission; G. W. Shannon, Anacortes; A. M. Bryant, Buckley; Frank T. McNitt, Centralia; Mr. Osgood, Everett; D. G. O'Brien, Seattle; C. W. J. Reckers, Seattle.

Monongahela Valley Retail Hardware Dealers' Association.

Under date of the 8th inst. the following circular was mailed to all retail hardware merchants in Western Pennsylvania by J. F. Frye, Charleroi, secretary of the Monongahela Valley Retail Hardware Dealers' Association:

That a closer social and business relation should exist among the Retail Hardware dealers of this State cannot be denied. In order to promote this greater fellow feeling, it is desired by many that a conference be called to which all legitimate retail dealers are cordially invited.

The place suggested is Pittsburgh, and the time, first week in December. Some of the officials of the National Retail Hardware Dealers' Association will be present at this meeting, and it is expected that much good to the retail trade will result therefrom.

Please state, on the inclosed postal, whether or not you can be present, and, after a sufficient number of replies have been received, you will be notified of the date of the conference.

The response to this circular, we are advised, has been so generous and encouraging that it has been decided to hold the conference in question in Pittsburgh on Tuesday, December 10. The place of meeting will be designated in a later circular.

If any of our readers in that section have failed to get a copy of the above circular, Mr. Frye requests that they send him their names and addresses, as it is desired to interest all legitimate retailers of hardware.

As indicated in the circular, several of the officials of

the National Retail Hardware Dealers' Association will be present at the meeting, which, it is expected, will develop much that will be of benefit to the trade in Western Pennsylvania.

Stove and Hardware Dealers.

THE AVERY STAMPING COMPANY, Cleveland, Ohio, have added a smaller sized Steel Spider to their line of Never-Break Cooking Utensils. It is designated as their No. 6 Breakfast Spider. The cooking surface of this size is 7 inches in diameter. It is referred to as very handy for cooking small quantities of ham and eggs, &c. The company state that they have encountered a demand for a Spider of this size, which is especially adapted for use in families where there is only a small meal to be cooked, and they are expecting to have a large sale of it.

THE GRAND MFG. COMPANY of Milwaukee, Wis., are about to put on the market a new Clothes Washing Machine which they call the Grand. It consists of a frame work supporting a tub made of galvanized iron. Within the tub there is a frame on which the clothes are laid and a roller which runs back and forth over the clothes to effect the washing. A sheet of water is thrown over the clothes each time the roller is operated. The roller is held in contact with the clothes by means of a spring which adjusts itself to the thickness. Under the galvanized iron tub an oil stove is provided for keeping the water in the tub hot while the washing is being done.

THE STAR ENAMELING & STAMPING WORKS, Allegheny, Pa., have been sold to a company who will remove the plant to McKeesport, Pa. The price paid was \$50,000.

MAINE MFG. COMPANY, Nashua, N. H., issue a folder, which they are ready to furnish to their customers in liberal quantities, printing in the name and address of the merchant. The folder is devoted to their White Mountain Refrigerators and attractively calls attention to the merits of this line.

MONARCH REFRIGERATOR WORKS, Burlington, Vt., have gotten out their illustrated catalogue and price-list for 1902 of the Monarch Dry Air Refrigerators, with removable and cleanable flues and removable ice chambers, zinc lined and nickeloid lined. Their line comprises Domestic, Sideboard, Water Cooler and Grocers' Refrigerators, Ice Chests, &c.

STURGES, CORNISH & BURN COMPANY, Chicago, have issued a Milk Can catalogue, which contains all their standard patterns of Railroad and Cheese Factory Milk Cans, together with their dairy line.

SHIPMAN, BRADT & Co., DeKalb, Ill., are distributing an illustrated price-list of their Hardware Delivery Wagons. The manufacturers call attention to the low down, short turn, high wheel, straight bottom, short coupled, light draft features of their Wagons. They have lately added to their line a new style Wagon, No. 63, which is referred to as just the Wagon for Stoves, Furnaces or any heavy goods. It is easy to load, the body being only 22 inches from the ground. Extension for ladders and spouting is furnished if desired. The Wagon is attractively finished and offered in four capacities, from 1000 to 2000 pounds.

The large plant of the National Enameling & Stamping Company in the Williamsburg section of Brooklyn, N. Y., was totally destroyed by fire at an early hour on Thursday morning, November 28. The factory occupied the block bounded by North First and North Second streets and Bedford and Driggs avenues. The origin of the fire is unknown. When discovered, at 2 o'clock in the morning, it had attained such strength that all the efforts of the fire department were unavailing to save the building. The night watchman of the plant lost his life in the conflagration. The factory was originally owned by the Haberman Mfg. Company, and was absorbed by the National Enameling & Stamping Company on the formation of that corporation. Over 700 hands were employed. A large amount of machinery, stock and finished goods was lost. The loss, which is heavy, is said to be entirely covered by insurance.

Vandergrift, a Workingman's Paradise.

The betterment of the workingman's condition is not a new idea. Many projects have been devised with this aim in view. Some of them have been fairly successful, while others have been dismal failures. The cause of these failures has not always been the same, but probably more can be traced to an imperfect comprehension of human nature by the projector than to any other single reason. Philanthropy is by no means a rare virtue, every community being blessed with individuals who are sincerely desirous of lightening the burdens and alleviating the distresses of their fellow creatures. But well meaning efforts in this direction are frequently of little practical value from a worldly point of view. The recipients of philanthropic attentions, who are not purely objects of charity, may accept the benefits of proffered assistance in bettering their condition, even if obligations are imposed upon them, but in time they will chafe under the feeling that they are being thus treated for an ulterior purpose and that they are losing their manly independence. As an example of a well conceived plan for the improvement of workmen, for enabling them to enjoy to probably the fullest possible extent the blessings, comforts and even luxuries of life compatible with the circumstances of wage earners, at the same time affording them perfect independence of action and the opportunity to develop individuality, the town of Vandergrift presents an unusually interesting study to the sociologist. It has been the extreme pleasure

of a representative of *The Metal Worker* to visit this town and to gather some facts concerning it, which are herewith presented, together with a number of illustrations.

How It Came Into Existence.

Vandergrift is located 38 miles east of Pittsburgh on the West Pennsylvania Railroad. It is in the beautiful valley of the Kiskiminetas, almost surrounded by thickly wooded hills. Here a tract of gently sloping ground, comprising 640 acres of farm land, was purchased a few years since by the Apollo Iron & Steel Company, now the American Sheet Steel Company, whose operations at Apollo, a short distance further up the river, had outgrown the space available for their works. Ground was broken for the new town in June, 1895, and simultaneously the construction of the new plant began. The first sheets rolled here were turned out on October 29, only four months after. The plant then consisted of 13 mills, but the business of the company speedily outgrew the capacity of the original works, and eight more mills were soon added, making 21. It was described in *The Metal Worker*, June 26, 1897. At present the construction of eight more mills is under way, so that the works will shortly have 29 in all. Nearly all the steel for these mills is produced in open hearth furnaces, which form part of the local plant. The annual output

of finished product, which will be greatly increased when the new mills are completed, has been 130,000 gross tons of sheet bars, 105,000 net tons of black sheets, and 170,000 net tons of galvanized sheets. The large output of galvanized sheets is due to the fact that all sheets intended to be galvanized are brought to the Vandergrift plant from the other works of the American Sheet Steel Company in the Kiskiminetas Valley, located at Apollo, Leechburg, Saltsburg and Hyde Park. The relative importance of these works is shown by their pay rolls, the Vandergrift works paying out \$1,500,000 per year in salaries and wages, Leechburg \$390,000, Apollo \$210,000, Hyde Park \$200,000, and Saltsburg \$150,000. The pay roll of the Vandergrift works will be increased 35 per cent. by February 1 next. It is the expectation of the management that this plant will continue to be en-

larged, it being their ambition to make it a 50-mill plant. The arrangement of the buildings will enable this to be done without impairing the original relations of the several departments.

A Great Industry Builds Up a Large Town.

The foregoing historical and statistical statements have been made in this connection for the purpose of enabling the reader to get a comprehensive grasp of the situation. So large an industrial undertaking could not have sprung up in the time mentioned, and on what was a farm when the first sod was broken, without attracting a large population to its vicinity. The town of Vandergrift now contains over 6000 inhabitants. While a roll foundry and some minor establishments have recently located there, the dependence of the citizens is so largely

based on the operations of the sheet mills that the latter must be closely considered in any observations made relative to the lives, habits and surroundings of the people.

When the managers of the Apollo Iron & Steel Company decided to build the new plant they also decided to lay out a town which would be so superior to the ordinary industrial settlement that it would attract a high class of workingmen. The financial benefits to accrue from the sale of lots were not overlooked, but this phase of the undertaking was made subordinate instead of paramount. The site selected was ideal. The mills were laid out on a comparatively level part of the tract. The ground set apart for the town slopes up gradually from the Kiskiminetas River, affording perfect conditions for drainage. The services of Frederick Law Olmsted, the famous landscape gardener, were secured in making the plan of the town. He laid out wide streets, not crossing each other at right angles, but forming arcs of a circle gently curving with the contour of the ground. The plan provided for a number of small plots to be ornamented with flower beds or shrubbery. Thus the beginning was made for artistic effect, which seems to have been deeply impressed on the minds and habits of the people. The lots as laid out were of good proportions, with an alley running through the center of every block.

GEORGE G. McMURRY,

The Founder of Vandergrift.

A complete system of sewerage was installed, pipes were laid for gas and water, connections were run to every lot to prevent the streets from again being torn up, and the streets and alleys were then paved handsomely and durably with vitrified brick. It was intended from the beginning that the town should have no outhouses.

Individual Tastes Consulted.

When all the preparations had been made, the men who expected to be employed in the mills were given the first opportunity to purchase lots. They had this preference for an entire week. The price made was the average price realized for five years for lots of the same size in the neighboring town of Apollo. No restriction was imposed on the purchasers save with regard to the sale of liquor. No liquor is permitted to be sold in the town. The lots were sold with no stipulation as to building lines or the character of the house to be built. Every man was permitted to be guided by his own taste. The company erected no houses and have none for rent, established no store and engaged in no branch of business outside of the manufacture of sheets, except such as were absolutely necessary in founding a new town. They organized a land company to look after real estate matters, as well as gas, water and electric light companies, but embarked in no line which brought them into competition with private enterprise. Further, no official, manager, superintendent or foreman can be interested in any business dependent to any extent upon the patronage of workmen. As soon as the workingmen purchased lots they consulted with their neighbors and established building lines or decided on uniform terraces in front of their houses where such were desirable. Instead of erecting plain or homely structures, they were inspired by their surroundings to study architectural graces, and numerous beautiful houses were built in the very infancy of the town. To-day it is one of the prettiest towns to be found anywhere. Every street is a revelation to the stranger who is familiar with other workingmen's towns. The houses are individualized, not built after a monotonous pattern. And they are tastefully and even artistically and luxuriously furnished. Nearly every house has its piano and its library, indicating the refining and elevating influences of the social life of the community. Every one, of course, has its own bathroom and other sanitary conveniences. The high character of the population is shown in the neatness with which the children are dressed.

Cheapness of Living.

The natural advantages of the locality add much to the charm of living in Vandergrift, which the workingmen themselves have named "a workingman's paradise." It is in a natural gas district, and every house uses this convenient fuel for cooking and heating, and sometimes for lighting, although electric light is generally used. Thus much of the labor and dirt incident to housekeeping are avoided. It is, further, only 3 miles from springs which have long been famous for the purity of their water. From these springs the supply of water is piped to the town. So excellent is the quality of this water that not a single case of typhoid fever has originated in the town from the date of its settlement. Coal is mined abundantly within a few miles and can be had cheaply for any purpose for which it may be required. The citizens thus enjoy great privileges, as may be seen from the statement made us by a housekeeper, whose house has ten rooms, all heated by a gas fired furnace in the basement, while all cooking and laundry work are also done with gas, that for four years the cost of his gas has yearly averaged \$34.46; electric light, \$16.83; water, \$12.75, and taxes, \$33.75.

The net rate for natural gas is 20 cents per 1000 cubic feet. The rate for electric light is 10 cents per 1000 watt hours, with a discount for prompt payment of 10 per cent. on bills under \$4 and 20 per cent. on bills over \$4 per month. The water consumed is measured by meter, the rates being based on the average rate of consumption for the preceding three months, ranging on a scale from 22½ cents per 100 cubic feet for 25 cubic feet per day to 6 cents per 100 cubic feet for 3000 cubic feet per

day, with 10 per cent. discount for prompt monthly payment.

The citizens govern the town, which has been incorporated as a borough under the laws of Pennsylvania. The officers thus elected by them have charge of the schools, look after the peace and good order of the community, and supervise all public improvements. They have erected good school houses, raising money for that purpose by issuing bonds, the land company donating the ground. The company also donated ground for four churches when the town was started, stipulating that each should cost not less than \$15,000, of which they further paid one-half. Since then several churches have been built by other denominations. The casino, which is a fine large building for public assemblies, was mainly built by the citizens. It cost \$32,000, the company donating the ground and \$14,000. In addition to assembly rooms it contains reading rooms and a fine free library having 2500 volumes. It is understood that the gas, water, electric light and telephone companies will be turned over to the citizens of Vandergrift if they desire and are prepared for municipal ownership.

The Character of the Workingmen.

As before remarked, the aim of the builders of Vandergrift was to attract a high class of workingmen. This they have succeeded in doing. It is, however, a remarkable settlement of young people. It is believed that in it hardly a dozen persons can be found over 50 years of age. The skilled men employed in the mills, from superintendents down, will not average over 32. This has not been brought about by any forced arrangement, but probably demonstrates that young men are more likely to settle in a new locality than old ones. Further, the workingmen are largely natives of the locality, sons of farmers or of workingmen in nearby towns. It is believed that not over 10 per cent. are foreigners, and these are principally employed in the galvanizing department, where the character of the work is distasteful to men fitted for a more skilled vocation. Among such a high class of workingmen a general spirit of good fellowship is shown. They freely and willingly assist one another, their intercourse being remarkably free from discord. Here the influence of the management and the power of a good example are seen. It is a cardinal principle in the Vandergrift works that every man shall be treated as a man, whatever his station may be. If a roller has a difference with a scrap boy, the superintendent gives a hearing to both, and if the scrap boy has been unjustly treated the roller is compelled to make amends. Any man having a grievance is invited to make it known to the management, and if on investigation the complaint proves to be well founded the trouble is corrected. All superintendents, to the highest, know the men personally so as to be able to call them by name and take pains to speak to them. Thus a bond of friendship and mutual interest is created and sustained. In the center of the plant, on its own separate plot of ground, stands a completely equipped emergency hospital, in which a trained nurse can be found day or night, ready to attend any one suddenly taken ill or injured. In serious cases a surgeon is summoned and is on hand in five minutes.

The Wise Policy of the Management.

The well being and prosperity of a town depend upon the steadiness with which the workingmen are employed. The happiness found in Vandergrift would be far less if the heads of families earned a precarious living or worked in an establishment which closed at frequent intervals. The policy of the managers is to run uninterruptedly, recognizing practically but two holidays in the year—namely, the Fourth of July and Christmas. They do not even shut down the customary four or five weeks for repairs in midsummer or midwinter. The sheet mills run in three turns of eight hours each, the last turn for the week ending at 8 o'clock on Saturday morning. This affords ample opportunity to change rolls, make repairs, clean out mill pits, &c. The open hearth, bar mill and galvanizing departments are run on two daily turns of 12 hours each. Care is taken to give every man a full day of rest each week. Day and night millwrights are employed, and a general cleaning up takes

place on Saturday, so that the machinery is always kept in good condition.

The men are paid on Friday, the money being taken to the mill and paid to each man wherever he is employed. He is not obliged to go to the office and stand in line. No roller pays the hands under him, but the company pay each man his own wages. Every one knows what is due him, as those who are paid on a tonnage basis receive a slip every day showing what they turned out the previous day, thus enabling them to check their accounts.

The works at Vandergrift are free works, no union rules being tolerated. The consequence is that the lucrative positions in the works are open to all who show fitness. It may be said that civil service applies here. If a new roller is needed, a man from some subordinate position is promoted. No union is permitted to send an unknown man from another mill, to keep the craft of rolling confined to a select circle. The same methods apply throughout all departments. Men are advanced as they display merit or special aptitude, and worth receives its proper recognition.

It is not surprising that men working under these conditions and with these surroundings were unwilling to strike when the effort was made to "call" them out last summer. Among such men agitators and fomentors of strife can obtain no foothold.

To Whom the Credit is Due.

All this has been largely due to the personal influence of George G. McMurtry, president of the company, whose genius for executive responsibilities was so signally demonstrated in the growth of the Apollo works. He saw that in the arrangement of that plant and of the town surrounding it many improvements were desirable for the betterment of the men employed, as well as for better results to the company. In studying this subject he visited many of the famous workingmen's towns in Europe, became thoroughly familiar with what had been done for workingmen, both abroad and in this country, and in time decided upon the methods which ought to be adopted in an American workingmen's town. They could not well be put in force at the old location, but could be at a new one. It was his desire to make his employees as comfortable and as happy as possible, and therefore he gave his personal supervision to the details. They realize this deep interest in their welfare and show their appreciation at every opportunity.

Coating Iron with Lead.

A new process for applying a coating of lead enamel to iron surfaces, recently invented by M. A. Dormody, is thus described in *La Nature*: The articles to be coated, after being heated to redness, are placed in a double hermetically sealed chamber with glazed sides; each half of the chamber can be worked alternately, and the surplus enamel powder, dusted over the metal by means of a sieve, is removed from the chamber by the draft from a high chimney. The necessary movements of the iron can be effected from the outside of the chamber, and the vibration of the sieves for the purpose of distributing the lead powder is provided for by an electrical beater.

THE UNIVERSAL SANITARY CUSPIDOR COMPANY, Worcester, Mass., are distributing circulars showing their Cuspidor and the method of using it. The article consists of a bowl having a cast iron flange designed to be set flush with the floor of public buildings. The main opening is protected by a central cast iron grating. The Cuspidor is provided with a trap beneath, so that it may connect with the plumbing system of a building, and is arranged for a water connection for thoroughly flushing the bowl. By this means, it is pointed out, greater cleanliness can be effected in hotel lobbies, stations, waiting rooms and large office buildings, where a number of people congregate. Setting flush with the floor it is claimed that, as it offers no obstruction, it cannot be upset and its contents spilled, and also that when the floor is mopped or washed the Cuspidor is flushed, so that greater cleanliness attends its use.

Situation in the Plumbing Trade.

The strained relations existing in the plumbing trade have called out a number of communications expressing various views in regard to the matter, to which we shall have occasion to refer in later issues. We take pleasure in laying before our readers at this time the letters given below, which are from men whose position in the trade entitles them to be regarded as thoroughly representative of the interests of the plumbers, whose action they defend as reasonable and necessary:

THE PLUMBERS' VIEW OF THE SITUATION.

To the Editor: I cannot agree with your editorial any more than I can with the Chicago Resolutions. You certainly are not well informed on the situation from our standpoint or your editorial would have taken a different tone. It is not true that the New York Conference Resolutions were granted the master plumbers to satisfy their demands, nor is it true that many of the manufacturers thought that they were granting us too much in adopting them. On the contrary, both we and the manufacturers realized at the time that we were giving them the large end of the deal. We did not ask them to pass them, but, on the contrary, they emanated from the manufacturers and we were asked to adopt them. We did this and realized at the time that we were giving them everything that they asked for, but at the same time we wanted for once to place the entire responsibility on their shoulders, and if they failed to carry out their part of the agreement it would be their fault and not ours. They were highly gratified when we passed the New York Conference Resolutions, for they really never expected that we would be willing to accede to anything so liberal to them. We faithfully lived up to our part of that agreement, and often at a sacrifice to ourselves, and they have never accused us of breaking our part of same. But they utterly failed to live up to their part of same, and did not even make a pretense of trying to do so. Had they carried out the provisions of the agreement, even to the extent of 75 per cent. of it, that agreement would be in existence to-day. But as they continually broke faith with us and would not enforce the penalties on their own members, even when the penalty was assessed by their own committee without a dissenting voice, we could only preserve our self respect by withdrawing from same. It was dead from their non-enforcement long before our committee met in Cleveland. Would you try to live up to a mutual agreement when the other side made no pretense of doing so? And, after all, we are only asking them to do what is only right and just. We ask of them that they shall not sell goods at both wholesale and retail—that they shall not sell us our supplies and then be our competitors also. We reserve the right to buy only from those whom we please, and we please to buy only from those who will confine their sales to legitimate channels.

REASONS FOR ADOPTING THE CLEVELAND RESOLUTIONS.

To the Editor: The New York and Cleveland Resolutions and your comments thereon have been carefully noted. The heading of your article refers to the radical stand taken by the National Executive Committee of Master Plumbers, but in my opinion the National Executive Committee of Master Plumbers were forced to take the position they did, in justice to their members. They had the right, and it seems to me they are perfectly justified in abrogating the New York Conference Resolutions. There was nothing else to do, after one of the contracting parties failed to act for over a year on several admitted violations of the joint resolutions on the part of their members.

I interpret the Cleveland Resolutions identical with the Baltimore, New York and Chicago Resolutions, with one exception, and that is, there are no provisions for arbitration jointly or for joint action in cases of disputes and infractions, a feature which seems to have been thoroughly and conscientiously tried with unfavorable results.

I fully believe that by conservative, prompt, business-

like and loyal measures under the Cleveland Resolutions proper trade protection can be secured by the manufacturers, jobbers and master plumbers in general.

Being one of the many who strenuously assisted in the adoption of the New York Conference Resolutions, especially on account of the mutual agreement of instituting a conciliatory committee, I very much regret, and in this coincide with all other local associations of master plumbers throughout our State and country, and especially the National Executive Committee of master plumbers, that a satisfactory result, under the circumstances, could not be obtained by such resolutions.

DUST CAUSES IMPURE AIR.

The influence of the dust deposited upon radiating surfaces on the purity of the air passing over them has not generally received the consideration which the final effect should secure for it. This has often led to the disparagement of some heating apparatus which a better knowledge of the cause would have avoided. The light thrown on the subject by the investigations of a German engineer should be of advantage to all who are engaged in heating with warm air. The results of his careful investigations are presented as follows:

It is well known that when a chamber system* of heating is started in the fall a bad odor is noticeable in the heated rooms, whether the surfaces have a temperature higher than 212 degrees or not. Many guesses have been made as to the cause of this. The reason most frequently offered was that the air was burned or dry distilled. But this answer must be rejected, for the reason that dry distillation can only take place at temperatures about three times as high as those attained in modern low pressure steam or hot water heating.

It remained for a German professor to look into the matter in the usually thorough German fashion. He made extensive investigations and tests of the dust gathered from the radiators in city residences and school rooms, and has evidently solved the problem. This investigation showed that the very fine carefully gathered dust is composed principally of horse manure, the presence of which is easily explained. This manure is ground into fine dust by the traffic and carried by the moving air and the shoes and clothes into the heating chambers and rooms, and naturally settles on the radiating surfaces.

It was further discovered that the dust taken from cold radiating surfaces had a large percentage of moisture, which is also easily explained. In view of the fact that this dust is composed largely of organic matter, and being highly hygroscopic, it is enabled to absorb large quantities of moisture. Last, but not least, the dust was found filled with micro-organisms. When these dust covered surfaces are slowly heated the moist manure, owing to the micro-organisms, will give off ammonia, which, on the one hand, gives to the air an unpleasant odor, and, on the other hand, has a bad effect on the mucous membranes of the people in the room. This would account for the belief that dry distillation of the air takes place, as the effect is quite the same. After a longer period of heating the moisture contained in the dust is withdrawn and the micro-organisms die. The evaporation of ammonia ceases, and with it the disagreeable effects noted above.

To avoid these altogether it is necessary to provide all heating surfaces with means for being properly cleaned and freed from dust before the beginning of any period of heating. It is further recommended to use only such radiation as is easily kept clean. Pin indirect or other extended surface radiation, and such sectional cast iron radiators as have the sections closely shoved together to save space, should be looked upon as unsanitary.

THE FOWLER RADIATOR COMPANY have secured land from the Lorain Steel Company for their plant at Johnstown, Pa. Portions of the old plant may be used.

* By chamber system the writer means a warm air furnace, or indirect steam or hot water heating system in which the radiation is inclosed in a chamber and has outside cold air duct.

HEATING SHIPS FROM SHORE PLANTS.

It has long been the custom of railroad companies to heat cars that are standing on a siding previous to their being run into the station to form trains for carrying people from a special steam plant operated for this purpose. A steam main, suitably insulated for protection against the loss of heat, is run along a track in the car yards, having outlets at places convenient for attaching steam hose connected with the car heaters. This has added greatly to the comfort of those who travel, and has also served as a protection to the cars themselves. It is now proposed by the steam engineering department of the Brooklyn Navy Yard to utilize a steam heating plant for heating ships which are undergoing repairs at the yard. Heretofore, when the boilers of ships were not in use it was impossible to heat them except by the use of stoves. This method involved discomfort and risk from fire. It is now intended to erect a suitable steam plant from which steam will be taken through mains in the yard, and from them by means of steam hose to radiators or coils in the vessels to be heated. It is expected that by this means a comfortable temperature can be maintained in the ship, so that workmen can more speedily make the needed repairs and a considerable saving may thus be affected. Heating by this process will also be cheaper and less laborious than when the boiler plants in the ships themselves are fired for the purpose.

THE CAST IRON SOIL PIPE SITUATION.

A meeting of the manufacturers of cast iron soil pipe and fittings was held last week at the Arena in New York City. The meeting lasted for two days, Thursday and Friday, November 21 and 22. Representatives were present of all the manufacturers in the United States, and reports were read by the permanent secretary to the manufacturers, Frank J. Mulcahy, which showed that the business during the fiscal year ending November 1, 1901, was profitable to the trade. In fact, it has been the most satisfactory year's business ever experienced in the history of the soil pipe and fittings industry. We learn that there was considerable discussion regarding a change in prices; some of the delegates being desirous of adopting a new scale of prices, which would be slightly higher than those now in effect. The majority of those present were of the opinion, however, that it would be impolitic and unwise to make any change at the present time, and that it would be to the best interest of all concerned in the manufacture and sale of this class of goods to maintain the present prices until the spring trade opens up. If the outlook warrants any change, it may be made at that time. Judging from present indications it is not improbable that there will be no change in prices either in the early spring or at any time before August or September of next year.

In November, 1900, the manufacturers of soil pipe and fittings entered into an agreement with each other whereby prices were to be maintained at a profitable and stable level. Rules and regulations regarding sales, shipments, freight allowances and territory were adopted, and allotments were made to the various foundries represented in the pool by which the producing capacity of each foundry was kept within a certain tonnage for one year, ending November, 1901. In no instance, however, was a prohibitive allotment made, the tonnage allowed each plant being much in excess of its apparent sales or demands.

The manufacturers were so well pleased with the manner in which the business of the association was handled that they have again signed similar articles of agreement, and will maintain prices and the same rules and regulations for another year from the date of signing the agreement. This news will be reassuring to the jobbing trade and also to those large contracting plumbers who, through the demands of their business operations, are compelled to carry large stocks of cast iron soil pipe and fittings at all times. The agreement between the manufacturers indicates that prices are likely to be kept on a steady basis, and that the market for

these goods will undergo no radical fluctuations in price for some time to come.

New York City Notes.

The question of working for general contractors on municipal work is one that has been brought prominently before the Master Plumbers' Association. Several city departments have made plumbing a separate contract, but some departments which have contracts to give out before the end of the year seem to have included plumbing in the general work. It is to be hoped that the plumbers have the means to prevent their work from being so included.

* * *

Morris Sandzik of 802 Second avenue, an unlicensed plumber, was held for trial in \$500 bail by Magistrate Mott on November 27 for doing plumbing work at 581 Third avenue. The association is making a determined effort to put these people out of business, unless they obtain certificates of competency, which most of them are unable to do. A number of other similar cases are under advisement.

* * *

The strike on the "Ansonia," the Stokes hotel, continues, owing to the difficulties between the two organizations of journeymen plumbers. Many efforts have been made to settle these differences, the latest being a new organization of the building trades, which claims to represent 65,000 men. They will form a new central body, leaving out all the warring factions in all trades.

* * *

C. D. McClure of 144th street and Willis avenue is a strenuous applicant for chief inspector of plumbing in the Bronx Building Department. He is endorsed by many prominent plumbers, but does not belong to the association. Numerous applicants are looking for the chief inspectorship in the other boroughs, and as the appointing power is as yet unknown, it is hoped that an organization man will succeed in getting the position.

* * *

Trade is about wound up on regular work. The supply trade are only filling the balance of orders, with the exception of the new jobs previously mentioned. All, however, are busy and looking for more work after January 1, when the new Tenement House law compels changes to be made in existing tenements.

* * *

Manhattan branch are making elaborate preparations for their entertainment and reception to be held on December 18, and expect one of the best affairs they have ever held.

Hot Water System Exhaust Heating.

Evans, Almlral & Co., 44 Dey street, New York, have prepared a catalogue dealing with their system of exhaust hot water heating. In this method hot water is used as the heating medium, being circulated through a system of mains similar in construction to those used in ordinary steam heating. In order to accelerate the natural circulation due to the difference in density of the water in the supply and return mains there is introduced in the circuit a small centrifugal pump driven either by belt, direct connected engine or motor. This insures a positive, rapid and perfectly controllable circulation in all parts of the system. Exhaust steam is used for heating the water, the method being such that there is absolutely no back pressure on the engines. The action is quite like that of a condenser, to which indeed the heater is similar in design. The water circulates in a space around the tubes, where it absorbs the heat of the exhaust steam, thereby condensing it. The condensed steam can afterward be either collected and returned to the boiler, or it can be allowed to go to waste. This exhaust heater can be placed so that it will utilize the exhaust steam from a condensing engine. This company have just received the contract for heating the large new shops of the Allis-Chalmers Works at Milwaukee.

The P. and S. S. League.

On Monday night the team of E. F. Keating succumbed to the teams of the Crane Company and the Ronalds & Johnson Company, Brooklyn, these two teams each winning and losing a game. The feature of the evening was the close contest in the last game, when the Ronalds & Johnson Company team scored 723 and beat the Crane Company team's score of 721. No games were on the schedule for Thanksgiving evening. The standing of the teams at the close of the second month of the tournament is as follows:

The Standing of the Teams for November.

Teams.	Won.	Lost.	Team Individual		Name.
			score.	score.	
John Simmons Company..	6	0	730	196	W. A. Presby.
Behrer & Co.....	5	1	827	198	M. Behrer.
F. N. Du Bols & Co.....	6	2	776	202	C. W. Frean.
Crane Company.....	4	2	727	210	A. E. Good.
Ronalds & Johnson Company, Brooklyn.....	4	2	827	195	R. V. Speres.
Salesmen	3	3	742	222	Henry Stein.
Ronalds & Johnson Company, New York.....	3	3	702	189	W. S. Gibbs.

Heating and Plumbing Notes.

THE L. H. TOUCEY COMPANY, Waterbury, Conn., are installing new Furnaces in the Methodist parsonage in that city and in the store of I. A. Spencer. They are also putting a new plumbing system into the residence of Mrs. I. L. Munson.

THE annual entertainment of the Manhattan branch of the Association of Master Plumbers of New York City will be given in the Lexington Opera House on Wednesday evening, December 18, under the auspices of the following Entertainment Committee: Milton Schnaier, B. F. Donohoe, T. J. McCormack, E. J. Brady, T. J. Cummins and John Boyd. *The Metal Worker* acknowledges the courtesy of complimentary tickets with an invitation to participate in the event.

THE JENNISON PLUMBING COMPANY of Fitchburg, Mass., have purchased the stock and business of F. N. Smith at Ayer. They have also purchased the building owned by Mr. Smith, in which they will conduct a branch of their plumbing business under the management of Mr. Smith.

THE KELLOGG-MACKAY-CAMERON COMPANY, 110 Lake street, Chicago, Ill., are sending to the trade a small hanger, showing the Little Giant, Improved Giant and Tropic Junior Water Heaters, designed for use in connection with hot water storage tanks, having capacity for supplying from 80 to 1300 gallons of water per hour. The hanger also shows a broken view of the company's Hot Water Storage Tanks, which can be furnished with or without steam coils. When furnished with steam coils they can be heated from the boilers in apartment houses during the time of year when these boilers are run or by means of a water heater during the summer season. These Storage Tanks are made in a variety of sizes, having capacity from 66 to 1000 gallons. The hanger also calls attention to an especially strong stand suited for vertical tanks and made in five sizes, from 18 to 36 inches in diameter.

THE authorities of Beverly, Mass., have passed a new plumbing ordinance.

ATTORNEY-GENERAL BELL of Texas objects to the statement that he agreed to the dismissal of the anti-trust suit against the Master Plumbers' Association of that State, but desires it stated that the plumbers will confess judgment for an agreed upon amount. Mr. Bell is also reported to have stated that the compromise will provide for the disorganization of the Plumbers' Association and the payment of a judgment satisfactory to the

Attorney-General. The amount has not yet been determined, but it is supposed that it will be small.

As a result of the violation of the plumbing regulations of Pittsburgh suit has been brought against a plumbing house in order to test the constitutionality of the plumbing laws in the courts.

F. E. BEHNER, Hartford, Conn., has the contract for installing hot air furnace heating systems in several houses that are being erected by T. P. Moulton and also in several houses for George M. Merrow.

Bids are being received by L. H. Focht of Reading, Pa., for the plumbing work in the Colonial Trust Building to be erected there, and also for the Philadelphia & Reading Railway Company's office building in the same city.

LEIGHTON & DAVENPORT of Bangor, Maine, have been awarded the contract for heating and ventilating the new Penobscot County Court House at their bid of \$5700.

THE CHARLOTTE PIPE & FOUNDRY COMPANY of Charlotte, N. C., have begun the erection of their new plant. The main building will be 100 x 100 feet and the machine shop 30 x 50 feet. Equipment for a daily production of 10 tons will be installed. J. J. Beggs is manager of the plant.

THE master plumbers of Davenport, Iowa, held a meeting recently to arrange for entertaining the State convention of the Iowa Masters Plumbers' Association, which is to be held in their city in February.

WORK is progressing on the addition to the foundry of the Iron City Sanitary Mfg. Company, Zella, Pa. The addition, 150 x 100 feet, is under roof and will be ready for operation by the first of the year, increasing the present capacity by 100 per cent. The foundations for a one-story warehouse, 80 x 100 feet, are completed and work on the structure will be started at once.

THE MONITOR STEAM GENERATING COMPANY, Philadelphia, Pa., have taken out city permits for the installation of steam heating plants at 815, 817 and 819 Girard avenue, in that city.

PHELPS BROTHERS, 284 Pearl street, New York, are making a specialty of the B. & A. Combination Union Elbow and the B. & A. Valves made by Blake & Andros of Boston, Mass. This firm handle a complete line of Steam and Hot Water Boilers, Pipe Covering and many Steam Specialties.

J. B. CARROLL, 36 La Salle street, Chicago, Ill., has issued a mailing card, one end of which is occupied by a picture that will receive more than passing notice. Under the picture are the words "A Head." This is followed by the statement that the Hahn Acetylene Gas Burner is far and away ahead in the production of light. The card also invites a trial of this Burner to ascertain its points of excellence.

THE MOLINE HEATING & CONSTRUCTION COMPANY, Moline, Ill., have completed a \$14,999 contract for laying a new main from the water works into the Stewartville section of the city.

W. G. SCHUWIRTH, San Antonio, Texas, bid \$14,435 for doing the plumbing in the houses and barrack of the Upper Post, and it is probable that he will secure the contract.

TAKING their cue from the recent events leading up to the settlement of the troubles in plumbing circles the master plumbers of Minneapolis, Minn., on November 18 voted to disband their association. The money in the treasury was divided among the members. According to the *Minneapolis Journal*, "This is said to be the end of all efforts on the part of the plumbers to get together on a scheme to throttle competition in the trade."

JACOB L. LAWRENCE of the firm of J. L. Lawrence & Sons, Sussex, N. J., died on November 22, aged 81 years. He had been engaged in the Hardware and plumbing business at Newton and Deckertown, N. J., for many years.

JAMES A. COOPER, formerly at the Youngstown Works of the National Tube Company, at Youngstown, Ohio, has resigned to take charge of the Tube mill of the Youngstown Iron, Sheet & Tube Company, now building

at Youngstown. James A. Hock of the Chester Works of the National Tube Company succeeds Mr. Cooper at Youngstown.

ATLAS PIPE WRENCH COMPANY, 121 Liberty street, New York, advise us that the sales of their Pipe Wrenches show a fine increase during the past few months, which, they state, is doubtless chiefly due to their exhibit at the Pan-American Exposition, in which a practical demonstration was given of the workings of the Wrench. They report that one of the jobbing houses in the Middle States has placed four orders for quantities of the Wrench in the past 40 days, a new stock order every ten days.

COL. WILLIAM P. TYLER, president of the Tyler Tube & Pipe Company of Washington, Pa., has returned from a six months' visit to Europe, greatly improved in health.

JAMES R. SMITH & Co. of Mechanicsville, N. Y., have removed their plumbing, steam and gas fitting business from Francis street to a store in the new Moore Block on Park avenue.

CHARLES S. HIRSCHFELD, who for the past two years has been manager of the Plumbers' Brass Goods department of Landers, Frary & Clark of New Britain, Conn., with headquarters at 82 Chambers street, New York, has tendered his resignation, to take effect on January 1. Until that date Mr. Hirschfeld will be at his post ready to do business for the firm. Mr. Hirschfeld, during the time that he has had charge of this branch of the company's business, has earned the esteem of the trade, for which he had previously laid foundations during his occupancy of the managership of the Plumbers' Supply department of the John Simmons Company of New York.

WILLIAM A. FOSKETT died at his residence at New Haven, Conn., on Thursday afternoon, aged 84 years. He was well known to the plumbing and heating trade from his long connection with it and his interest in the Foscett & Bishop Company.

New Firms and Changes.

THE STANDARD LIGHT COMPANY of Wilmington, Del., have been incorporated, with a capital of \$500,000, for the purpose of manufacturing Incandescent and other Burners.

THE GEORGE D. FITZSIMMONS PLUMBING & HEATING COMPANY have been incorporated in St. Louis, Mo., with a capital of \$10,000, the shares being valued at \$100 each. Ninety-eight of the shares are held by George D. Fitzsimmons and one share each by A. F. Fitzsimmons and F. Bauer.

F. JOHN McCASKER, who has been Inspector of Plumbing at Montgomery, Ala., for a number of years, has resigned his position and will open a plumbing and steam and gas fitting establishment at 14 South Ferry street in that city.

THE ANCHOR SANITARY COMPANY is the name of a new concern in the Plumbing Supply business at Pittsburgh, Pa. O. C. G. Brettell is the president; T. J. Duncan, vice-president; J. B. Lantz, secretary; H. L. Andrews, treasurer, and John F. Bailey, manager. The new company expect to be ready for business the first of the year. They have all been connected with plumbing supply houses and are thoroughly familiar with the business, Mr. Andrews having acted as purchasing agent for a large concern for a number of years.

E. I. P. STEADE has sold to W. Funk an interest in the Mankato Plumbing & Heating Company at Mankato, Minn.

THE CURTIS SHEET STEEL & CORRUGATING COMPANY, Zanesville, Ohio, manufacturers of Black and Galvanized Sheets and Painted Corrugated Roofing, rolled their first Sheets on October 24, and advise us they have been running two hot mills ever since, without a single break. They are also rolling their own Bars, the Bar mill having been started October 17, and this also has run very satisfactorily, nothing so far having been broken. They are shipping about a carload of Sheets per day and have a good many orders on their books.

AMERICAN EXHIBITION IN ENGLAND.

United States Consul-General Osborne of London has sent to the State Department the prospectus of the American Exhibition, which is to be held at the Crystal Palace, Sydenham, from May to September, 1902. The Consul-General states that the exhibition is well backed, and has an Influential American Advisory Committee. The Crystal Palace, in which the first international exposition was held fifty years ago, is a very large building, and is particularly well adapted to such a purpose. The buildings cover about 16 acres, are all perfectly lighted, heated and ventilated, and are surrounded by the most beautiful ornamental grounds in Europe, extending over 200 acres. Practically the whole of the interior of the palace will be devoted to the exhibition, which it is expected will prove of benefit, commercially and socially, to both the United States and Great Britain.

In connection with the exhibition it is proposed to establish, under the direction of a committee of representative Americans and British firms, a Commercial Bureau, so that all necessary information may be supplied to exhibitors in regard to the channels of trade and the placing of goods upon British and Continental markets. For the convenience of exhibitors, arrangements will be made with a well-known firm for the supply of stands or cases for exhibits, either to order or to hire at moderate rates. Exhibitors, however, will be at liberty to make their own arrangements in this respect. The American Exhibition of 1902, which is the official title of the proposed undertaking, is designed, according to the prospectus, to demonstrate the immense commercial development which has taken place in the United States during recent years, and it will be the largest and most important exhibition of American products, arts, industries and inventions yet seen in the United Kingdom. The various departments of exhibits, as classified, include in Class 1, machinery and all matters pertaining to the mechanical industry. Class 6 embraces hygiene, lighting, heating, ventilating and sanitary appliances.

The rules governing the exhibition, with form of application and plans of the Crystal Palace, have been filed for reference in the Bureau of Foreign Commerce at Washington, D. C., and plans and particulars of space, charges for which range from about \$1 to \$5 per square foot, according to position, will be forwarded on application to the Assistant Commissioner for Commercial Section, 20 Victoria street, London, S. W., or to the General Manager, Crystal Palace, London, S. E.

Rust Removers.

The following rust removers are recommended in the directions issued to the United States Artillery:

Cyanide of potash is most excellent for removing rust and should be made much use of. Instruments of polished steel may be cleaned as follows: First, soak, if possible, in a solution of cyanide of potassium in the proportion of 1 ounce of cyanide to 4 ounces of water. Allow this to act until all loose rust is removed, and then polish with cyanide soap. The cyanide soap referred to is made as follows: Potassium cyanide, precipitated chalk, white castile soap. Make a saturated solution of the cyanide and add chalk sufficient to make a creamy paste. Add the soap, cut in fine shavings, and thoroughly incorporate in a mortar. When the mixture is stiff cease to add soap. It may be well to state that potassium cyanide is a violent poison.

For removing rust from iron the following is given: Iron may be quickly and easily cleaned by dipping in or washing with nitric acid 1 part, muriatic acid 1 part and water 12 parts. After using wash with clean water.

An estimate prepared by a Philadelphia banking house shows that there remains in the anthracite fields of Pennsylvania 5,073,775,000 tons of unmined coal. Almost the whole of this coal is owned by the eight railroad companies that operate in the anthracite territory. It is estimated that 50,000,000 tons of anthracite coal will be mined and marketed this year.

CHIMNEY TOPS AND VENTILATORS.

The first chimney made by man did so much for his comfort in removing the smoke and gases and other products of combustion from his habitation that the chimney ever since has been an important feature of all buildings. The early smoke ducts had some features which are essential in all chimneys, even at this point of progress in the inventions of mankind. These features embraced the provision of a flue practically straight from top to bottom, and of a rectangular shape, which seldom departed from an absolute square. As the use of houses became more general, and in localities where they were grouped closely together, some liberties, however, were taken with the size and shape of the chimney. In some cases a step backward to the habitation of the aborigines, in which the smoke got out of the domicile through the same opening by which the owner entered, seems to have been taken and smoky chimneys were a frequent subject of complaint. This led to the study of the top of the chimney, when it was found that the shape of the top had not a little to do with the rapidity of the up current within the chimney, commonly characterized as draft. Where some buildings in a group were higher than others it was found necessary to arrange the top of the lower chimneys so as to be proof against back drafts and to aid the escape from them of the rising products of combustion.

Those who ride through large cities cannot fail to notice that mankind has been making strenuous efforts to help the chimney. The chimney top, or ventilator, is made in a variety of styles, and the chimney expert is frequently called upon to exercise his art in this field. David J. Rosen, 439 Canal street, New York, who has made a study of the chimney problem for a number of years, has invented and is manufacturing the Russo side draft ventilator, which, he claims, meets all requirements. This ventilator has been attached with satisfactory effect to the top of a short chimney in the middle of a low, narrow building standing between two very high buildings, so that when a high wind causes a strong current to rush across the roof of the low building it creates an exhaust in the chimney instead of having a baffling effect upon the heating apparatus to which it is attached. Low chimneys naturally do not have the strength of draft of higher chimneys, and chimneys in the surroundings described frequently fail in operation. The Russo chimney cap or side draft ventilator is designed to utilize the force of these air currents to effect an exhaust from the chimney, so as to draw away from the fire the gas and smoke produced by combustion. This ventilator also utilizes the heated air rising along the outside of the chimney top for effecting an exhaust draft from the chimney, even when there is an absolute stillness of the air, when many constructions for the relief of chimneys prove a hindrance to the draft.

Those who sell stoves, either for heating or cooking, hot air furnaces or steam and hot water heaters are subject to more or less complaint when the results from the apparatus are less satisfactory than expected. In many instances the cause of the trouble is with the chimney, and a study of the operation of chimneys and the methods of applying a remedy when trouble is reported is important. In such cases points can often be secured by following the course which has been pursued successfully by others. A short ride on any one of the elevated roads of New York City will convince the most skeptical that a "long felt want" has been supplied by the chimney cap or ventilator.

A remarkable project is now receiving the attention of Russian engineers. It is proposed to construct a tunnel under the main chain of the Caucasus Mountains from a point 40 miles south of Vladikavaz. The tunnel will be 23 miles long, and its estimated cost is \$75,000,000. It is believed that the scheme, which has the warm support of the Czar, will be taken in hand as soon as the Trans-Siberian Railway is finished. The work will be of vast importance, as it will afford direct communication between Southern Russia and Trans-Caucasia.

FAMINE IN SPOT TIN.

Of all metals tin is the most erratic in movement, subject to violent speculation, sudden, sharp and wide fluctuations of prices, periodical corners and what not. At times trading is attended by great excitement, at others the mood of the market is as gentle as a lamb. Taken all in all, tin—pig tin—affords as many opportunities for profit and loss as the stock market, and as many elements of chance enter into its barter as bewilder the guests of Monte Carlo.

The relative scarcity of tin and its mining in widely separated districts throughout the world make possible peculiar and dramatic situations. But with all the provoking eccentricities the nurries in tin are of an ephemeral nature—too intense to last long.

It is only within very recent years that this country has been directly and intimately connected with the rise and fall of tin, although always indirectly interested. But with the growth of the tin plate industry the market for pig tin has become a matter of the greatest importance and solicitude to domestic dealers and consumers.

Recent statistics reveal the rapid, large and important increase in the domestic manufacture of tin andterne plates. In 1900 about 302,000 tons were produced, against 18,000 tons in 1892, while imports decreased from about 330,000 tons, valued at \$24,000,000, in 1890, to 60,000 tons, worth less than \$5,000,000, in 1900.

In the present state of unprecedented activity in iron and the active demand experienced for its close relations, such as steel and tin plate, a corner in pig tin is of more than usual interest.

Ordinarily it is London that sets the other markets of the world ablaze, and not infrequently Singapore offers a surprise, but at present New York is feeling the effects of a famine in spot tin in which the other tin markets, consumptive and productive, are but little interested, the conditions prevailing being entirely of a local character.

From November 1 to 24 the arrivals of pig tin at the port of New York were scarcely sufficient to meet the consumptive requirements for one week. But two weeks ago it became evident that the spot supply was short and the light stocks were found concentrated in the hands of one firm, who have cornered the local market on several previous occasions.

The delay of steamers laden with tin has aggravated the situation and added to the distress of dealers dependent upon the stock in transit to make November deliveries. Naturally there has been an heroic effort made by consumers to remain out of the market, all sorts of expedients being resorted to. But wants became so pressing, and efforts to borrow or beg unavailing, that on Monday some consumers were forced to purchase supplies at prices 5 cents per pound higher than were current on November 8.

The arrival of the steamer "Jupiter" on Saturday last gave some slight relief to the hungry market, and there is now afloat from Singapore, Penang, Rotterdam and Southampton over 3000 tons. The steamers in transit, with the exception of two, should have arrived at Atlantic ports on various dates prior to November 24; the other two are due on December 2 and 7.

Seldom, if ever, has the New York market had conditions like the present to contend against, but while the situation is unusual and the solicitude of consumers acute, with a further advance in prices probable before substantial relief comes, the days of the corner are numbered by a few. Still, even with a more ample supply, the urgent demand for immediate delivery may hold the spot market strong, however unsettled it may become for future delivery.

HUTCHINSON LUMBER & SUPPLY COMPANY, Valdosta, Ga., wholesale Hardware, Lumber, Machinery, &c., advise us that they would be pleased to receive catalogues and price-lists relating to Hardware, Tinware and Mill Supplies.

TRADE NOTES.

WILLIAM A. BROWN, for many years treasurer of the Jos. Dixon Crucible Company of Jersey City, N. J., and formerly a member of the Board of Public Works in that city, died at Asbury Park, N. J., on November 22, after a long illness, aged 66 years.

THE SELF SEALING CAN COMPANY, with office at 15 Exchange place, Jersey City, N. J., have been incorporated, with a capital stock of \$5000, by Lemuel A. Welles, Alfred J. Curtiss, Harold Walker, Nathan Smyth and John J. Treacy, to manufacture Cans, &c.

THE ST. LOUIS SUNLIGHT COMPANY of Arkadelphia, Ark., have been incorporated by C. E. Neely, R. G. Speer, John R. Boddie and George H. Loeke, with a capital of \$5000, to sell machines for the generation of illuminating gas.

THE PRESSED METAL & NOVELTY MFG. COMPANY have been incorporated at Baltimore, Md., with a capital stock of \$5000, for the manufacture of Pressed Metal Novelties. Frank Ruckle, Adolph Meyer, George A. Macauley and others are interested.

THE LUDLOW TIN TAG WORKS of Ludlow, Ky., have combined with similar plants at Chicago, Ill., and Durham, N. C., and the three plants will be consolidated at Ludlow, employing 300 men.

THE SCOVILL MFG. COMPANY, Waterbury, Conn., manufacturers of Brass and German Silver Sheets, Rods, &c., have already installed eight stands of 20-inch rolls in their new rolling mill, which was put in operation in September, and there are emplacements provided for four stands of 16-inch rolls which they expect to have in operation by February. Most of the work was built by the Bethlehem Steel Company and the engine was furnished by the Southwark Foundry & Machine Company of Philadelphia. The company at the present time are enlarging their Wire mill.

POWERS BROS., Henry, Ill., report constantly increasing sales of their Powers Automatic Chimney Tops and Iron Mountings, on which they advise us that they have an established trade in Canada and all over this country.

THE PITTSBURGH LAMP, BRASS & GLASS COMPANY have been incorporated under New Jersey laws, with a capital of \$1,500,000, to manufacture and deal in Lamps and Glassware of all kinds. The incorporators are James H. Willock, Frank G. Wallace, George W. Blair, George B. Barrett, Nicholas K. Opp, Wm. Curray, David W. McMaugher and Edward A. Fitzmiller, all of Camden, N. J.

SARGENT & Co., New Haven, Conn., and 149-153 Leonard street, New York, in a 16-page 13½ x 8½ inch folder in legal document form, just issued, describe the "What, Why and How" of Sargent's Gem Food Chopper. The first portion illustrates and describes the Chopper in its various details. Then follows a series of 14 prepared advertisements of various kinds and sizes adapted for use in the local newspaper or other medium. Sargent & Co. are ready to furnish these cuts, with the dealer's name and address inserted in space at bottom of advertisement, free of charge on application.

THE W. J. CLARK COMPANY, Salem, Ohio, have just completed the building of a brass foundry. About seven years ago they began the manufacture in a small way of an improved Hose Coupling, now quite extensively known as the Quick as Wink Coupler for fire, lawn and mechanical hose. The almost universal belief that the old style screw coupling could never be excelled made the introduction of the Quick as Wink Coupler a hard task, but it grew in favor with fire departments steadily, though slowly, so that its superiority to the old style coupling is pretty well known. Still, the demand for them was too limited until more recently to justify installing a brass casting department. Therefore the castings for these Couplers were contracted for at Pittsburgh and elsewhere. The discovery about two years ago that Quick as Wink Couplers on air hose were time savers in shops where compressed air is used has increased their sales, so that they have been compelled to establish a brass foundry of their own.

Intersection of Elliptical Pipe and Scalene Cone.

A New York correspondent desires a solution of a problem on which he has been working for some time without success. It is the intersection of an elliptical pipe and a scalene cone, as in Fig. 1, where A B C is the elevation of the scalene cone, and D E F G its plan, taken on the line B C of the elevation, while H I J B shows the outline of the elliptical pipe placed in plan, as shown by K L M F. To obtain the miter line in elevation between the pipe and cone proceed as follows: Divide one-half of the plan F G D into equal spaces, as shown by the small figures 1 to 8, and draw lines to the apex F in plan, intersecting the half plan of the pipe

P R, as shown from 1 to 8 to 1, because the spaces in F K L M in plan are unequal. At right angles to P R and from the small figures draw lines, as shown, which intersect with others (not shown) drawn at right angles to H B in elevation from similar numbered intersections on the miter line B J. Trace a line through points of intersection thus obtained; then will P R S T U be the pattern for the elliptical pipe.

Before obtaining the pattern for the scalene cone it will be necessary to obtain a diagram of triangles from which the pattern is obtained, for which proceed as follows: Let the triangle A B C and the half plan F G D, with the various intersections on same in Fig. 2, be a reproduction of the triangle and half plan having similar letters in Fig. 1. Now, with F as center, Fig. 2, and radii, equal to F 2, F 3, F 4, F 5, &c., to F 7, draw arcs intersecting the line F D at points 2' to 7'. These various

Fig. 1.—Plan, Elevation and Pattern.

INTERSECTION OF ELLIPTICAL PIPE AND SCALENE CONE.

F K L at points 1, 2', 3', 4', 5', 6', 7' and 8'. At right angles to F D and from points 1 to 8 on F G D erect lines intersecting the base line of the cone in elevation, as shown, from which intersections draw lines to the apex A. Next intersect these radial lines in elevation with others (not shown) drawn from the intersections 1, 2', 3', 4', 5', 6', 7' and 8' on F K L in plan at right angles to F D, intersecting similar numbered lines in elevation shown by 1'' to 8''. Trace a line, as shown by B J, through points thus obtained, which will show the miter line or intersection between the scalene cone and elliptical pipe. Parallel to A B draw the line V W, upon which place the various heights of the intersections in the miter line B J from points 1'' to 8'' at right angles to A B, as shown from 1° to 8° on V W. This will be used in the diagram of triangles in Fig. 2.

For the pattern for the elliptical pipe draw any line, as P R, in line with H I, upon which place the stretch-out of the elliptical section F K L M in plan, being careful to carry each space separately onto the line

lengths represent the base lines of the various triangles which will be constructed by erecting lines at right angles to F D from points 1, 2', 3', 4', 5', 6', 7' and 8, intersecting the base line B C at 1'', 2'', 3'', 4'', 5'', 6'', 7'' and 8''; from these intersections draw lines to the apex A. Take the various heights on V W in elevation, Fig. 1, and place them on the line A B of Fig. 2, placing the point 1° on the point 1'' on the base line B C. Then at right angles to A B and from the various points 1° to 8° draw lines, as shown, intersecting the hypotenuses of triangles having similar numbers, as shown by intersections 2x to 8x. Next, with A as center and radii equal to A 1'', A 2'', A 3'', &c., to A 8'', draw arcs, as shown. Now set the dividers equal to the spaces contained in the half plan F G D, and, starting on the arc 1'' at 1, step from one arc to another, or, in other words, starting on the arc 1'' at 1, step to arc 2'', then to 3'', until the point 8 is obtained on arc 8'', which repeat, going backward, until the point 1 on the arc 1'' is obtained. Trace a line, as shown by H I J. Again using A as center and A 2x, 3x, 4x, 5x, 6x, 7x and 8x as radii, intersect radial lines in pattern drawn from the small figures on H I J to the center A, thus obtaining the intersections 2''' to 8''' to 2''' in pattern. Trace a line, as shown by J K L M H, and H I J K L M H will be the pattern for the scalene cone.

A CHARTER has been granted by the Secretary of State of Pennsylvania to the West Carnegie Sheet Steel Company, which concern took the place of the Carnegie Sheet Iron Company, chartered some months ago. A change in the *personnel* of the company caused the directors to apply for another charter under a new name. The directors of the West Carnegie Sheet Steel Com-

pany are: George W. Wilson, former director of the Department of Public Works of Pittsburgh; City Treasurer David H. Torrence, W. H. Skivington, Joseph R. Paull and George M. Chalfant, all of Pittsburgh. The company have secured 11 acres of land in West Carnegie, Pa., on which they will erect a ten-mill plant to cost about \$400,000. The plans for the building are now being prepared, and the company expect to have the plant in operation by the middle of next year.

Tests of New Tin Plate Process.

Regarding the Allis-Andrew tin plate process, with which the American Tin Plate Company are experi-

The packs are reduced to 31-gauge at one heat, in five passes, and without any opening or doubling in the operation. There are other improvements in the Allis-Andrew system which make a still further reduction in the cost of manufacturing tin plate and sheets which at present the American Tin Plate Company have not facilities for testing.

H. Herbert Andrew, J. P., managing director of J. H. Andrew & Co., Limited (Toledo Steel Works), Sheffield, England, was here during the first demonstrations and sailed for Liverpool Saturday last. Mr. Andrew represents the British capitalists interested in the Allis-Andrew system, and will lead a movement to revolutionize the manufacture of tin plate in Wales.

New Sheet Rolling Process.

Albert J. Demmler of Wellsville, Ohio, has just obtained a patent on what may turn out to be an important improvement in rolling sheets. Mr. Demmler's idea, according to the *American Manufacturer*, is to provide means for maintaining a pile of heated sheet or plate metal at approximately the proper temperature for rolling, and prevent such rapid cooling of them as would render the sheets in the lower part of the pile too cool for the operation.

In a patent granted to W. M. Theobald in 1898, a process of bluing sheet iron or steel was set forth, which consisted of exposing the sheets to the atmosphere by turning them over one at a time and forming a pile of sheets by placing one turned over sheet upon the other, then taking the pile to the rolls and passing one or two sheets at a time while their temperature was above 300 degrees F. One difficulty with this practice has been that the sheets in the lower part of the pile were liable to cool during the rolling of the sheets above them so as to be brought below the proper temperature for fixing the oxide on the surface or polishing them.

The object of Mr. Demmler's invention is to provide means for holding a mass or a pile of sheets or plates at the proper temperature, so that the sheets in the lower part of the pile will not lose their heat so rapidly as to be lowered below the proper rolling temperature, the invention being intended for use in warm rolling, either for bluing or polishing, or in the rolling of the sheet or plate metal at higher temperatures, such as at a practically red heat, to reduce the same to thinner gauge.

To these several ends the invention consists, generally stated, in the combination with a set of sheet rolls of a hot bed adapted to support a pile of heated sheets or plates placed in position to feed the same to the rolls, so that when the pile of sheets is placed on the bed it will aid in maintaining the heat of the sheets in the pile as they are fed to the rolls. The invention is employed with any suitable form of sheet rolls mounted in housing, the hot bed being preferably located directly in front of the rolls.

The hot bed is formed of a frame supporting a heated metal slab, on which the pile of sheets rests. This hot metal slab is preferably heated in the furnace with the sheets to be treated, the idea being to carry the sheets on the slabs on which they rest while being heated, either in the furnace or within the annealing box, to the rolls, so that the sheets are not disturbed from the time they are built up upon the slab and inserted in the furnace until they are fed directly to the rolls, the slabs thus forming the support for the sheets in the furnace and the means for carrying them to the rolls and acting at the rolls as a hot bed for maintaining the heat within the pile of sheets as the top sheets are fed one by one to the rolls. Such slabs are preferably made of cast steel plates of sufficient thickness to fully support the sheets in handling and to store the necessary heat to maintain the mass of sheets in the pile at the proper heat for rolling.

The hot bed may be in the form of a suitable portable furnace, carried on rollers and built of brick work within a suitable casing and having extending over the top the slab on which the pile of sheets rests. For heating the bed a series of gas jets may be employed that play upon the slab and maintain it at the proper heat.

Fig. 2.—Plan, Diagram of Triangles and Pattern. . . .

INTERSECTION OF ELLIPTICAL PIPE AND SCALENE CONE.

menting at their United States works at Demmler, Pa., the Pittsburgh Dispatch of November 24, says:

Thomas V. Allis of Bridgeport, Conn., president of the International Tin Plate Corporation, is here to continue some very successful demonstrations of manufacturing tin plate and sheets by the Allis-Andrew system which are being conducted for the American Tin Plate Company at their United States Works.

The tests of this new system were commenced at the Demmler plant some ten days ago, and were so satisfactory that more extended operations were desired. Thus far all indications point to the justification of Mr. Allis' claims, that with the present heating and rolling capacity of the American Tin Plate Company he can more than double the present output, thereby saving fully \$5 per ton.

Where it is not practicable to use gas a thin coke fire will serve the purpose. The hot bed is made portable, so that it may be adjusted in position for the proper feeding of the sheets to the set of rolls, such position depending upon whether the sheets are to be simply warm rolled, as above referred to, or whether they are to be hot rolled and passed more than once between the rolls, in the latter case the hot bed being removably drawn back from the set of rolls or placed at one side thereof.

Joseph W. Britton.

Joseph W. Britton, for many years prominently identified with the manufacturing interests of Cleveland, Ohio, died in that city on the 22d inst., aged 72 years. The cause of his death was a stroke of paralysis, which occurred several months since. Mr. Britton was born in New Hampshire in February, 1829. He removed to Cleveland in 1853, and was for a number of years with his father, one of the pioneer Western railroad builders. The Brittons built a division of the Atlantic & Great Western broad gauge railroad and a number of other lines. In the late fifties J. W. Britton, with Samuel Mather and others, established the old Cleveland Boiler Plate Mill, one of the earliest plants of its kind in the city. Later he became associated with the Cleveland Rolling Mills in Newburg, being for 11 years manager of the plate and sheet mills. Then, with Ralph Hickox, he bought back the boiler plate mills, of which he had been one of the founders, and operated the plant for a number of years under the name of the Britton Iron & Steel Company. During his early connection with this company he saw the necessity for and invented a machine for leveling sheet iron. For this invention he was awarded a gold medal at the International Inventors' Exposition, held in London in 1885. Mr. Britton continued at the head of this company until 1891, when he sold his interest in the business to John D. Rockefeller. Meanwhile he had made, at the mills that bore his name, the first steel plates for shipbuilding produced on the great lakes. After selling out to Mr. Rockefeller Mr. Britton established the Britton Rolling Mills, near Gordon Park, and at them made the first tin plates produced in Cleveland. When the American Tin Plate Company were formed he sold his mills to them, and since then had given his attention to mining interests in Colorado and Canada. Mr. Britton leaves a widow, five sons and three daughters.

FLASHINGS.

THE GIBRALTAR PAINT & ROOFING COMPANY of Syracuse, N. Y., have been incorporated with a capital of \$30,000 by William D. Bannon, F. K. Smith and Thomas Dougherty of Syracuse.

GEORGE CALLAHAN & Co., 218 Front street, New York, send us a folder showing the different shades in which they can furnish their Silicate of Iron Paint, which, under the name Egyptian, is put up ready mixed in cans of different size for painting buildings. A special feature of the Paint is claimed to be its adaptability for use on Galvanized Iron Cornices, to which it is said to adhere and stand the ravages of time without peeling.

THE bimonthly conference on the Tin Plate wage scale was held in Pittsburgh last week. An examination of the books of the American Tin Plate Company showed that the Tin Plate workers were entitled to no advance in wages.

HARRISON BROTHERS & Co., Philadelphia, Pa., issue a 24-page pamphlet devoted to their Antoxide Paints for coating Iron and Steel surfaces. The catalogue is illustrated with half-tone engravings, showing ships, railroad bridges and water works stand pipes which have been coated with the company's Paints. One page in the catalogue treats of their Antoxide Paint, which is said to adhere firmly to Galvanized Iron, making the best priming for coating this troublesome surface.

It is reported that the officials of the Amalgamated Association of Iron, Steel and Tin Workers are considering a proposition to erect a new building as a headquarters for the association. In case the plan should be

carried through it is considered probable that the headquarters may be removed from Pittsburgh.

THE WILLIAM CONNORS PAINT MFG. COMPANY, Troy, N. Y., makers of the American Seal Paints and Cements, inform us that they make a Paint which is especially adapted for painting Galvanized Iron work. This Paint is put up in packages of different sizes, convenient for the use of Cornice makers and all who have to paint Galvanized Iron. They also make a special Cement suited for Slate, Tile and Metal Roofs.

CHARLES B. BURDETTE will erect a two-story brick Tinware factory, 40 x 100 feet, in Baltimore, Md.

GEORGE D. EVANS, heretofore connected with the American Tin Plate Company's mill at Lisbon, Ohio, has become superintendent of the Carnahan Tin Plate & Sheet Company's new plant, in course of erection at Canton, Ohio. Work is being rapidly pushed upon this plant, and it is stated that three of the mills will probably be ready to begin turning out Tin Plate next week. The other three mills will follow a week or two later. A number of skilled men have been secured from Leechburg, Newcastle and Kensington, Pa.; Lisbon, Ohio, and Elwood, Ind. The unskilled labor will probably be hired in Canton.

It is rumored that the American Can Company purpose doubling the capacity of their Tin Can plant at Fairhaven, Wash., before next season. A number of the officials of the American Can Company have been visiting their properties on the Pacific Coast during the past week or two.

THE MANVILLE COVERING COMPANY, Milwaukee, Wis., have been awarded the contract for Asbestos Roofing Matting for covering all the buildings of the new plant of the Allis-Chalmers Company in that city.

THE GEORGE B. WEAST MFG. COMPANY, Harrisburg, Pa., inform us that the damage done by fire recently at their plant has been fully repaired, and that the plant is now in full operation, with bright prospects of running for an indefinite period, in order to fill the large number of orders on file and those which are coming in. The company manufacture Corrugated Expanding Conductors and Eave Troughs, and make a specialty of Pipe for heating and ventilating, blast, air and blower work.

A. W. BURDICK & Co., Memphis, Tenn., inform us that they have the contract for the Galvanized Iron Cornice, Skylight, and 145 squares of Tin Roofing for St Joseph's Hospital in that city. They are putting the Copper Valleys, Gutters, Galvanized Cornice and Skylights, and 155 squares of Slate Roofing, on St. Mary's Church. The company are also putting a Slate roof and Galvanized Cornice work on the St. Joseph's Orphan Asylum, the Seventh Street Church and the Hunter department store, and are doing similar work on a number of residences in their city. They report that business has been better this year than ever before, with bright prospects for work well into February.

THE Board of Trade of Parkersburg, W. Va., are offering inducements to the Wheeling Roofing & Cornice Company of Wheeling to locate in Parkersburg. The company, who contemplate the erection of an extensive plant in the spring, have also had propositions from New Martinsville, W. Va., and other towns.

THE BROWNE SLATE & METAL COMPANY of Galveston, Texas, who make a specialty of Slate and Tile Roofing, Galvanized Iron Cornices and Skylights, report that they have had an exceptionally good business during the fall.

THE W. DEWEES WOOD COMPANY works of the American Sheet Steel Company, at McKeesport, Pa., were operated on Saturday night, November 23, the first time this has been done for some years. Like all other plants of the American Sheet Steel Company, this works are crowded with orders and were run on Saturday night in order to get out as much material as possible.

THE Tin Plate workers of the Amalgamated Association have voted almost unanimously against the proposition to have the Tin Plate scale hold for three years from July 1, 1901. The officials of the American Tin Plate Company have been notified of the decision, and the Tin Plate scale will therefore terminate on June 30, 1902.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

WANTS REMEDY FOR SINGING BALL COCK.

From P. & T., Hightstown, N. J.—Kindly publish in *The Metal Worker* a remedy for a singing valve in a closet tank. This is the supply valve, and operates under a street pressure of 60 pounds.

Note.—We trust our readers will give their experience in overcoming this trouble, which is frequently reported. In the meantime we would state that inquiry has disclosed the fact that the singing is more frequently reported in connection with top supply valves, and that the trouble is seldom reported with supply valves that are located in the bottom of the closet tank. The trouble is primarily due to the vibration caused by the flow of water through the valve as the opening becomes reduced, and the ball cock gets unsteady in its movement, owing to the decreasing and intermittent flow. The noise resulting therefrom is deadened when the valve is in the bottom of the tank, with several inches of water above it. When a top supply valve is used there is nothing to deaden the noise, and if the piping is very rigid or tightly attached so as to be on something of a tension or strain, the noise will be intensified. An examination of the ball cock, so as to tighten all its parts and remove anything that may hinder the valve closing without friction, may overcome the trouble reported.

PROPORTIONS FOR DELIVERY MILK CANS.

From Proportionist, Devon, England.—I should be glad to have some of my fellow subscribers to *The Metal Worker* inform me of the dimensions or proportions of the sheet metal cans used for delivering milk, such as would give proportions that will provide an attractive appearance. One may make such a can, and after it is finished it will not look smart enough to be called attractive. The top or neck may be too large or too small, or the body too squat, and I shall be glad if those who have made such goods would give their views on the proportions of their most shapely delivery cans and other dairy fixtures.

WEIGHTS OF TERNE PLATES.

From J. M., Baltimore, Md.—I would thank you if you can inform me through your valued journal whether the makers of IC 20 x 28 terne plates have a regular standard or basis or uniform weight of black sheets before they are coated, as I should like to be able to determine what a box of tin should weigh. I have bought plates on the representation of carrying 40 pounds, 30 pounds and 8 pounds coating to the box. For instance, I have recently bought a lot of 20 x 28 ternes said to carry 40 pounds of coating, and I find that the weight per box ranges from 235 to 244 pounds. I have also experienced other variations in the different grades of terne plates. Are these variations in the black sheets, or in the coating, or in both? Any light that you may throw on the subject will, I believe, be appreciated by many of the readers of *The Metal Worker*, as well as myself.

Answer.—The manufacturers of terne plates calculate to use black sheets having a base weight of 200 to 204 pounds for each box of 20 x 28 plates. With 40 pounds of coating, the finished plates should, therefore, weigh from 240 to 244 pounds. According to the United States standard gauge, which is used by all sheet manufacturers, a variation of $2\frac{1}{2}$ per cent. either way is allowed on every 100 pounds; consequently, the difference referred to by our correspondent, amounting to 9 pounds in boxes of plates supposed to carry 40 pounds of coating per box, is within this limit. Some variation of weight is also in-

evitable in connection with the coating, as it is practically impossible to make the weight of coating absolute in boxes of heavily coated terne plates. In the cases mentioned, the variation would probably be due both to the black sheets and the coating. Recognizing this possible variation, the American Tin Plate Company are careful to classify their terne plates as "about" 40 pounds, 30 pounds, &c., of coating. In the case of a lot of boxes of plates, it is understood that the average weight should correspond pretty closely to the basis named—that is, their average weight should be from 240 to 244 pounds. If, in buying a quantity of plates, the average weight of the boxes is found to fall short of this standard, the customer would probably have a claim upon the manufacturers for short weight.

PAINT FOR GALVANIZED IRON.

From B. B. C., Temple, Texas.—We wish to inquire of the readers of *The Metal Worker* if there is any paint known to the trade that will stick to galvanized iron. Our experience has been that within a year after the application of a coat of paint it will scale off. Does the galvanizing prevent the absorption of the paint, or is it due to some chemical action between the paint and the zinc forming the coating?

Note.—We shall be glad if our readers will render such assistance as they can to this correspondent. In the meantime we would suggest that it has been the opinion of those who have previously contributed to *The Metal Worker* that it is better for the galvanized iron to be exposed to the weather for a short time, in order that the gloss and any grease or acid that may be on the iron may be washed off by the rain, or removed by the effects of the weather, before a coat of paint is applied.

HOW MANY FEET OF CARBON GAS CAN BE MADE FROM ONE CUBIC FOOT OF GASOLINE?

From W. & Co., Chariton, Iowa.—Can *The Metal Worker* or some of its readers inform us how many cubic feet of carbon gas can be produced from 1 cubic foot of gasoline? We do not refer to hydrocarbon gas, but gas developed by heat without any percentage of air.

Answer.—We have no data in regard to making a permanent gas by the decomposition of gasoline by heat. It is not economical, which may account for the want of literature on this subject. From analogy with the gas production from the heavier oils, we can only estimate that gasoline will yield about 50 cubic feet of permanent gas from 1 cubic foot of the liquid.

PLATING STEEL WITH STEEL.

From W. J., Wappinger's Falls, N. Y.—Can you give me any information as to how to plate steel onto steel? For instance: I have a piece of solid steel with little pin holes below the surface and I want to fill them. How shall I work the battery?

Answer.—We fear that our correspondent will not be able to fill pin holes in steel by the electric process. The electroplating by steel on a plain steel surface is somewhat difficult, but is used on copper plates for producing a hard wearing surface; the steel deposit being very hard but brittle. It can only be made in a very thin layer. The solutions and process are described in "Brant's Metal Worker's Handy Book."

The recent enactment of a law in Great Britain prohibiting the use of poisonous white lead in the pottery industry has brought forth a protest from a number of English manufacturers, who consider the law nearly impossible to comply with. United States Consul Bergh, at Gothenburg, Sweden, in a recent report to the State Department says, however, that at the Rorstrand porcelain factory in Sweden, and at a large factory in Dresden, Germany, this important technical problem has been successfully solved by mixing the white lead in the glazing with certain substances, converting the lead into an insoluble—and thus harmless—silicate of lead.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin has advanced sharply and rules from 2c. to 2½c. higher.

Copper is dull and unchanged.

Pig Lead is dull and firm.

Spelter is quiet and slightly firmer in price.

Antimony is unchanged.

Nickel continues firm and active.

Aluminum is active at former prices.

Tin Plates are quiet and without change.

Sheets are in heavy demand; jobbing prices on Black Sheets are slightly lower.

Sheet Copper continues firm and in good demand.

Pig Iron is in active demand and very strong; some brands have been advanced in price.

Hardware is moving actively and the market is very steady.

Plumbers' Supplies are in good demand and prices strong, especially on Iron Goods.

Cast Iron Soil Pipe and Fittings are firm; prices having been reaffirmed.

Solder prices were advanced 2c.

Wire Nails are somewhat irregular in price.

Cut Nail prices were reaffirmed for December; demand is moderate.

Wire is still in good demand and prices firm.

Window Glass prices are being cut some by jobbers.

White Lead is unchanged in price and in good demand.

Linseed Oil has declined 5c. a gallon.

Spirits Turpentine is firm and unchanged.

METAL MARKET.

NEW YORK, November 29, 1901.

Pig Tin.—As a result of the corner in spot Tin, mentioned in our last report, prices have been forced up during the week to extreme figures and the scarcity is more keenly felt than ever. Arrivals of Tin this week amounted to 450 tons, bringing the total for the month to date up to 1100 tons. Jobbers have advanced their prices on small lots of Straits Pig to 34c. to 34½c. per lb. The market was strong at the close, with a possibility of still higher prices before the end of the week.

Copper.—Rumors were rife again during the week regarding a prospective cut in prices of Copper. The report came from the Wall street district, however, and has thus far proved to be unfounded. Owing to depression of the Amalgamated Copper stock interest the situation has become more acute. As to trade conditions, however, the situation is unchanged. Prices remain at their former level and the demand is of limited proportions. Small lots of Lake Copper are quoted by jobbers at 17¼c. to 17½c. and Casting Copper at 16¼c. to 17c. per lb.

Sheet Copper.—There is no change in the general condition of this article. The demand is of good proportions and prices remain firm on the basis of 21c. per lb. for Sheet Copper from store.

Pig Lead.—Dullness is the feature of the demand for Pig Lead and prices are without change. American Pig in small lots is quoted at 4.55c. to 4.60c. per lb. St. Louis advices report continued quietness in the Pig Lead market there, without any change in the volume of demand or sale.

Spelter.—The market for Spelter is quiet and steady. Western brands in small lots are quoted at 4.55c. to 4.60c. per lb. St. Louis reports a firmer tendency in the Spelter market. The fact that the production of the smelters is sold well ahead is brought out more forcibly

from day to day. It is pointed out that at the present time the production does not seem equal to the demand, and higher prices are looked for.

Sheet Zinc.—A moderate demand is noted in Sheet Zinc, prices being unchanged. Jobbers quote 600-lb. cask lots at 6¼c. per lb., and smaller quantities at 7¼c.

Antimony.—No change has taken place in this metal. Cookson's in small parcels is quoted at 10½c. to 11c., and Hallett's at 8½c. to 9c. per lb.

Nickel.—Is unchanged, prices continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—The demand for Aluminum continues active. Prices remain at 37c. per lb. for small lots of No. 1 Ingot, guaranteed 99 per cent. pure, and 35c. for 100-lb. lots.

Tin Plate.—The market for Tin Plates is absolutely without change of any sort. Deliveries are still hardly up to the measure of requirements, although the latter are limited. In a retail way, Tin Plates are selling in fair volume in hand to mouth lots. Large buyers apparently have covered their requirements for the next few months. Jobbers' prices are inclined to ease off. American Bessemer Coke Plates, IC, 14 x 20, are quoted at about \$5.65 to \$6.15 per box. The American Tin Plate Company are selling only for the first quarter of next year. A further decline of 3 pence per box in the price of Welsh Plates was reported this week.

Sheets.—Heavy contracts are being placed for both Black and Galvanized Sheets for delivery next year, prices to be the same as those in force by the leading Sheet interest at the time deliveries are made on these contracts. Three or four new Sheet plants are just about ready to start and are soliciting business for next year. The mills are still unable to make deliveries as promptly as required. Prices on Black Sheets are slightly easier, No. 27 One Pass Cold Rolled Soft Steel Sheets being quoted in small lots at about 4.05c. A heavy demand for Galvanized Sheets is noted. The market is firm at 65 per cent. to 67½ per cent. off the list.

Chicago advices are as follows: There is some guessing as to what effect the opening of new mills early in the coming year will have upon prices, but even with this in prospect business continues very active. There is difficulty in obtaining spot deliveries on some sizes and prices are without quotable change, though fluctuating, No. 27 Common ranging from 3.50c. to 3.70c., from store, and Galvanized from 65 and 10 to 70.

Old Metals.—A fairly active demand is noted for Scrap Iron, but prices are without change. Scrap Brass and Copper are moving in pretty good volume at former prices. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb. 14¾c.
Light and Tinned Copper.....	per lb. 12¾c.
Heavy Brass.....	per lb. 9¼c.
Light Brass.....	per lb. 7½c.
Lead.....	per lb. 4 c.
Tea Lead.....	per lb. 3½c.
Zinc.....	per lb. 2¾c.
No. 1 Pewter.....	per lb. 17½c.
No. 2 Pewter.....	per lb. 8½c.
Tin Plate Scrap, per gross ton.....	\$6.50 to \$7.00
Wrought Iron Scrap, per gross ton.....	10.50 to 11.00
Heavy Cast Scrap, per gross ton.....	10.25 to 10.50
Stove Plate Scrap, per gross ton.....	7.25 to 7.50
Burnt Iron, per gross ton.....	5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—Consumers are not only covering their requirements pretty generally for the opening months of the coming year, but some of the most important Eastern foundrymen are seriously considering the question now of making contracts to cover their entire necessities for 1902. The disappearance of stocks at the furnaces and the maintenance of an excellent condition of general business are causing them to feel somewhat apprehensive.

hensive about the course of prices, and they feel that it will be wise to protect themselves. Northern Irons have been marked up to some extent and our quotations are revised accordingly. We quote: No. 1, \$16.35 to \$17.50; No. 2 X, \$15.65 to \$16; No. 2 Plain, \$15.15 to \$16; Tennessee and Alabama brands, No. 1 Foundry, \$16; No. 2 Foundry, \$15.25; No. 1 Soft, \$16; No. 2 Soft, \$15.25; No. 3 Foundry, \$14.75; No. 4 Foundry, \$14.25.

CHICAGO.—The general impression is that the big buying for the first half of the year is over. Some makers are practically out of the market, but there remains a considerable number of the smaller melters who have not covered their wants much, if any, beyond January 1. A fair trade has been experienced this week, largely for quick shipment and small lots. The closing down of furnaces unexpectedly, putting out of this market about 5000 tons of Pig Iron a week, which had been sold and was depended upon for delivery, has resulted in a scarcity of stock, making shipments on old contracts scarce. Prices of Southern products have been strengthened and prices, as corrected, are as follows:

Lake Superior Charcoal.....	\$17.00 to	\$18.00
Local Coke Foundry, No. 1.....	15.50 to	16.00
Local Coke Foundry, No. 2.....	15.00 to	15.50
Local Coke Foundry, No. 3.....	14.50 to	15.00
Local Scotch, No. 1.....	15.50 to	16.00
Ohio Strong Softeners, No. 1.....	17.25 to	17.50
Southern Silvery, according to Silicon.	16.15 to	16.40
Southern Coke, No. 1.....	15.65 to	16.15
Southern Coke, No. 2.....	15.15 to	15.65
Southern Coke, No. 3.....	14.65 to	15.15
Southern Coke, No. 1 Soft.....	15.65 to	16.15
Southern Coke, No. 2 Soft.....	15.15 to	15.65

PHILADELPHIA.—Iron for prompt delivery is scarce, and prices are close to the highest of the entire year. The situation is under the complete control of producers. The business of the past week may be said to be entirely satisfactory. A considerable amount of Iron has been taken for the first three and first six months of the coming year. Prices are just about as they were a week ago, the undertone being decidedly firm at the following figures for Philadelphia and nearby deliveries, and about 25c. less for deliveries within a radius of 100 miles south or west: No. 1 X Foundry, \$15.75 to \$16; No. 2 X Foundry, \$15.50 to \$15.75; No. 2 Plain, \$15 to \$15.25.

PITTSBURGH.—Many consumers are in distress for Pig Iron, the furnaces not being able to get cars to ship out their Iron as fast as needed by their customers. The situation in Iron is very strong, and spot metal is bringing from 25c. to 50c. a ton premium. No. 2 Foundry Iron, for prompt delivery, is sold at \$15.75 to \$16, Pittsburgh, for small lots. On contracts for next year's delivery, No. 2 Foundry has been sold at \$15.50 to \$15.75, and No. 1 at \$16 to \$16.50.

CINCINNATI.—There has been a very good run of trade in Pig Iron throughout the past week. Most of the tonnage is for the second quarter next year delivery. The current inquiry bespeaks a continuation of the present activity. Quotations for Southern Irons are unchanged, and, when the quality is taken strictly into consideration, there is but one basis upon which to figure. The prices on Lake Superior Coke brands were advanced to preserve the same relation to Southern Iron as formerly. The situation is exceedingly strong, and while a conservative spirit is evident, yet it looks as though there would be further advances before the prevailing activity ceases. The scarcity of cars is still causing considerable annoyance. We quote, f.o.b. Cincinnati:

Southern Coke, No. 1.....	to	\$15.00
Southern Coke, No. 2.....	to	14.25
Southern Coke, No. 3.....	to	13.75
Southern Coke, No. 4.....	to	13.25
Southern Coke, No. 1 Soft.....	to	15.00
Southern Coke, No. 2 Soft.....	to	14.25
Southern Coke, Gray Forge.....	to	13.25
Southern Coke, Mottled.....	to	13.25
Ohio Silvery, No. 1.....	\$15.35 to	15.85
Ohio Silvery, No. 2.....	14.85 to	15.35
Lake Superior Coke, No. 1.....	15.85 to	16.35
Lake Superior Coke, No. 2.....	15.35 to	15.85
Lake Superior Coke, No. 3.....	14.85 to	15.35

ST. LOUIS.—Conditions in the Pig Iron market continue along about the same lines as last reported. A very good and steady demand ruling, with no marked let up on account of the recent advance. No large orders come to light this week, single lots of 500 tons being about the heaviest that can be noted. The Coke supply among the Southern furnaces seems to be causing considerable uneasiness, and while it has not as-

sumed a very serious phase the railroads do not seem to be in any better condition to meet heavy requirements for cars at this time. We quote as follows for cash, f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$15.50 to	\$15.75
Southern, No. 2 Foundry.....	14.75 to	15.00
Southern, No. 3 Foundry.....	14.25 to	14.50
Southern, No. 4 Foundry.....	13.75 to	14.00

CHICAGO REPORT.

Scrap Iron and Steel.—The dealers in Old Material held a meeting in New York City on the 21st inst., but have not as yet made any public report of their proceedings. The trade are awaiting the report of this meeting with considerable interest. The demand is fairly active, especially for Stove Plate, which is decidedly scarce. We quote dealers' buying prices in car-load lots, Chicago delivery, as follows:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast.....	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	5.50 to 6.00
Burnt Iron and Grate Bars.....	6.00 to 7.00
Sheet Iron and Hoops.....	9.00 to 10.00
Plow Steel.....	9.00 to 10.00
Breaking Stock.....	6.00 to 7.00
No. 2, such as Shovels, Hoes, &c.....	6.00 to 7.00
Old Boilers—whole (Iron).....	9.00 to 10.00
Old Boilers (Iron) cut in single Sheets and Rings.....	10.50 to 11.50
Old Gas Pipe and Boiler Tubes.....	4.50 to 5.00
Cast Borings.....	9.50 to 10.00
Turnings.....	to 13.00
Horseshoes.....	

Old Metals.—The demand for Tin Foil has been very heavy and price has been advanced to 22c. Pewter is also higher. Dealers quote buying prices on small lots as follows:

	Per lb.
Copper Wire and Heavy.....	14 3/4 c.
Copper Bottoms.....	13 1/4 c.
Copper Clips.....	14 1/4 c.
Red Brass.....	13 3/4 c.
Yellow Brass.....	9 1/2 c.
Red Brass Borings.....	11 1/2 c.
Yellow Brass Borings.....	8 1/2 c.
Light Brass.....	7 1/2 c.
Pipe Lead.....	4 c.
Tea Lead.....	3 1/4 c.
Zinc.....	2.80 c.
Tin Foil.....	22 c.
Pewter, No. 1.....	18 c.
Pewter, No. 2.....	15 c.

Old Rubber.—The surplus in Rubber Shoes noted in last report continues, and while the price is unchanged, it is weak and is likely to go lower. We quote as follows:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7 1/2 c.
Rubber Car Springs.....	5 1/2 c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	7 1/4 c.
Black Rubber.....	4 1/4 c.
White Rubber.....	8 1/2 c.

Rags.—No change to note. Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at 75c. to 85c. per 100 lbs. in any quantity.

Anthracite Coal.—There is a scarcity of Chestnut Coal and continued complaint on account of shortage of cars. Prices for December are unchanged, as follows:

	Grate.	Egg and Stove.
Chicago.....	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

THE HARDWARE TRADE.

The past week has been comparatively uneventful, as business has run along in regular channels without any important change in general features of the market or in the prices of leading goods. The activity which has prevailed continues without interruption, and manufacturers and merchants, from the producers of the raw material down to the retailers of the finished goods, are fully engrossed in attending to the demands of current business. There is thus on all sides a very satisfactory conditions of things. The lines in which the larger volume of business is doing are season goods on which the jobbers and larger retailers are covering their requirements for next year. Steel Goods, Lawn Mowers, Scythes, Freez-

ers, Refrigerators, Window Screens, Wire Cloth, Poultry Netting, &c., are thus receiving the careful attention of buyers. In this class of goods many of the jobbers are endeavoring to secure the orders of the better class of retail merchants who order well in advance of their requirements, and at relatively close prices on many of these lines, which in some cases cover delivery. The tone of the market is very steady, and in some lines is decidedly strong. The firmness of the Iron market and the difficulty which manufacturers experience in obtaining raw material have a perceptible effect on Hardware prices. There is little buying beyond expected requirements, in anticipation of advances, and there is thus little speculation going on, but there is a confident feeling that most goods can be bought with safety, and the probability that in some lines there will be more or less of a shortage has influence in inducing merchants to place orders early and for liberal quantities.

NOTES ON PRICES.

Plumbers' Supplies.—The advance of the season brings a natural falling off in the demand for Plumbers' and Steam Fitters' Supplies. Yet considerably more business is still coming in to the supply houses than is usual at this late period. Prices in all lines are firm, with indications of a possible advance in some goods, owing to the scarcity of Iron and the consequent strength of the Iron market.

Sanitary Earthen Ware.—Rumors have been current during the past few weeks to the effect that the price of Sanitary Earthen Ware would suffer a decline in the immediate future, owing, it is said, to the disbandment of the Potters' Association. It is true that potteries are now being erected, and some are already in active operation, which are not represented in the association and which are selling their output at prices slightly below the association prices. It is said to be equally true that the wares of the outside plants are not up to the standards established by first-class manufacturers of this line of goods. The goods, it is claimed, lack shape, finish and glaze, and cannot be marketed at the price established by the association, owing to the fact that, where all prices are equal, the trade will send their orders where they can get superior goods at the same price. It seems probable that the Potters' Association will continue for another year and, according to good authorities in the trade, prices of Sanitary Earthen Ware are likely to be maintained on a steady level.

Cast Iron Soil Pipe.—As noted in another column, the manufacturers of Cast Iron Soil Pipe and Fittings, at a recent meeting, reaffirmed the present prices on these goods. The market presents a firm appearance, and no change in prices is looked for in either direction for some time to come.

Solder.—The rapid upward movement in Pig Tin during the week has been accompanied by a corresponding rise in the price of Solder. Manufacturers have advanced their quotations from 1½ to 2 cents per pound. Half and Half Solder, in small lots, is now quoted at 19½ to 20 cents, and No. 1 at 16½ to 17 cents per pound.

Wire Nails.—The Wire Nail market shows no change in general conditions. There is more or less irregularity in price. Small lots from store are selling at \$2.35 to \$2.40 per keg.

Cut Nails.—At a meeting of the Cut Nail Association held last week existing prices were reaffirmed for the month of December. The local demand for Cut Nails continues normal, and the market shows increased firmness. Representatives of mills are adhering to the price of \$2.25 for Nails from store, while jobbers in some instances are selling at 2 cents below these figures in New York.

Wire.—Makers of Fence and Poultry Netting are placing large orders for Wire, having sold large quantities of their goods for delivery next year. Prices are somewhat uneven, and more or less shading is said to be going on, depending on order and point of delivery. Small

lots of Plain Wire in New York are quoted at 2.55 to 2.60 cents, and Galvanized at 2.95 to 3 cents.

Window Glass.—As a result of a meeting held last week between the combined manufacturers and the Window Glass Jobbers' Association, the prices of the latter to the trade were reduced to apply to the entire list of single and double strength all over the country. The discount on less than car lots from store was fixed at 90 per cent. Since the new discount has been in effect, local prices from store have been cut, in some cases, to 90 and 10 per cent. discount.

White Lead.—The demand for White Lead in Oil for completing outside work has constituted the larger part of the business in the local market during the week. No change has been made in quotations, although reports of concessions of from ¼ to ½ cent are current. In a retail way White Lead in Oil is selling at 7 to 7¼ cents per pound.

Linseed Oil.—During the week the increase of available Linseed Oil has become marked, while consumption has shown a decrease incident to the season. Prices have fallen off about 5 cents per barrel and Raw Oil is now quoted in small lots at 56 to 56½ cents per gallon. Boiled Oil is 2 cents advance on Raw. The Oil market has thus quickly changed from a strong position to a weak one, and a further decline in price would not come as a surprise.

Spirits Turpentine.—The market for Turpentine continues steady and quiet, with quotations unchanged. The Southern market is steady and firm. Moderate sized lots from store are quoted at from 38 to 39 cents per gallon.

New Publication.

HAND BOOK OF PRACTICAL MECHANICS. By Charles H. Saunders, Ph.B. Price, \$1. D. Van Nostrand, Publishers, New York, 1901.

This Hand Book of Practical Mechanics is intended for use in the shop and drawing office. It contains tables, rules and formulas and the solution of practical problems by quick and simple methods. The book opens with an extensive alphabetical index occupying 30 pages. In dealing with the subject of the teeth of gear wheels, diametrical pitch is defined, also arc pitch, pitch diameter, &c., and after the definition in each case there follows an example which makes the point clear. A table of diametrical pitch, with corresponding circular pitches, depth and thickness of teeth, is given, in which the thickness and depth of teeth are intended for use with the Brown & Sharpe patent cutters. The method of finding outside diameter and angles of bevel gears is exemplified with numerous formulas, also rules for calculating the strength of the teeth of gear wheels. The method of laying out involute teeth is explained, and is illustrated by an appropriate sketch. A few pages are devoted to the elucidation of logarithms, with a table of common logarithms from 1 to 100.

Problems connected with worm gear are dealt with in a number of paragraphs, which are followed by a table of natural sines, cosines and tangents.

Under the heading of Areas of Plane Figures, the triangle and circle are treated, and a table of diameter, area and circumference of circles is introduced. Among screw threads, we find, grouped together with formula, illustration and tables, the United States standard, the international or metric thread, the sharp V, the Whitworth, the British Association thread, and the Acme standard screw thread, followed by a series of tables bearing upon bolts, nuts, taps and drills. Pulleys, shafting and belting, with rules, tables and various items of useful information, succeed the consideration of screw threads, and the related subject of lathe thread cutting follows, being preceded by the rule for computing the horse-power of an engine.

The weights of iron and steel sheets, neatly tabulated, is followed by a table giving the equivalents of the United States standard gauge for sheet and plate iron and steel. A number of workshop receipts, which practical men will appreciate, are set down. United States weights and measures, the metric system, with English

equivalents, weights and areas of round, square and hexagon steel, and a table of sizes and weights of square and hexagon nuts occupy adjacent paragraphs. The latter pages of the book contain various tables useful in shop and drawing office.

If there is any fault to be found in the arrangement of the various subjects dealt with, purely from a compiler's standpoint, the comprehensive index with which the book opens fully meets this criticism by furnishing the practical mechanic or draftsman with the means of turning directly to the matter with which he is concerned at the moment. The book contains information on a great variety of subjects, and with its rules, examples, tables and useful hints, should be most acceptable to those whose wants it is designed to meet. It is now in the second edition, and the author has, as he tells us, endeavored to add, in the present work, such information as has been suggested from time to time, and yet has preserved the condensed form, which readily commends it to practical men, for constant use.

A Southern Sheet Plant.

The Maryland Sheet & Steel Company is the name of a concern which took out papers of incorporation this week in New Jersey. The temporary offices of the company are given as 41 Market street, Camden, N. J. The charter permits the company to manufacture steel, sheets, &c. The capitalization is placed at \$100,000, but, according to reports, this amount will be increased. The incorporators are: Albert F. Baumgarten of Pittsburgh, Howard H. Dickey, Harry E. Weber, Robert R. Henderson and Charles E. Metz. It is understood that Philadelphia capital is backing up the enterprise. The company have purchased and will operate the plant of the Crucible Steel Company of America, at Cumberland, Md., converting it into a sheet mill, where they will make sheets from No. 14 gauge up.

United States Consular Agent Harris writes from Eibenstock, Germany, that within the past two years the German colonial school at Wilhelmshof, in Witzendhausen, has educated and sent 25 young men to German East and Southwest Africa, Kameroun, Togo, South Sea Islands, Ecuador, Brazil, Philippines, Cape Colony and Sumatra. The course of study given in this school is as follows: History, colonial economics, commercial politics, chemistry, botany, geology, natural history, tropical climates, tropical agriculture, bookkeeping and gardening, with special attention to raising vegetables, fruit and vines and forestry. A chemical laboratory, a blacksmith, a locksmith, a cabinet making, and other departments have been arranged, where work is practiced as taught.

United States Consul Bergh, at Gothenburg, reports to the State Department that the Vislanda-Bolmen Railroad of Sweden recently made an experiment with pressed and dried peat as fuel with an extra train consisting of locomotive, 15 loaded freight cars and one passenger car. The distance was about 22 miles, and the time table was set for lower speed than the ordinary, but this extra train arrived in due time at the respective stations, and at the final station 15 minutes ahead of time. Considering the fact that the locomotive in use was built for using coal only, the result of the trial is regarded as very satisfactory.

The Kansas State Board of Agriculture announces that the winter wheat yield in Kansas for 1901 was 90,045,514 bushels, valued at \$50,479,570. This breaks last year's State record by 13,450,070 bushels. The area now sown in winter wheat is nearly 6,000,000 acres, which with favorable weather will yield more than 100,000,000 bushels. The corn crop in Kansas in 1901 was only 42,605,672 bushels, but the value of the combined wheat and corn crops was only 11.3 per cent. less than that of the same crops in 1900.

In his report for the fiscal year ended June 30 last, Secretary of the Interior Hitchcock says that although

one-third of the land of the United States is vacant, there is but little of this fitted for homes. He recommends that the Government immediately take hold of the proposed irrigation of the 600,000,000 acres of arid land in the West, beginning the work with that already mapped out in the preliminary surveys.

A scarcity of lumber is being felt in the building trade of the East. Hard woods and the higher grades of lumber are specially hard to obtain. It is said that the mills are overcrowded with orders, and cannot turn out their product fast enough to meet the requirements of their customers.

President Samuel Gompers has issued a call for the twenty-first annual convention of the American Federation of Labor, which will meet in Scranton, Pa., on Thursday, December 5.

Sea Green, 1/2 sq.	\$2.00 @ \$3.15
Purple, 1/2 sq.	3.75 @ 4.25
Unfading Green, 1/2 sq.	3.25 @ 4.50
Red, 1/2 sq.	6.50 @ 11.00

Brownville, Unfading Black:

No. 1 quality.	\$5.25 @ 7.50
No. 2 quality.	\$4.25 @ 6.00

Solder—

1/2 lb guaranteed.	19 1/2¢ @ 20¢
No. 1.	18 1/2¢ @ 17 1/2¢

Prices of Solder indicated by private brands vary according to composition.

Soldering Fluids—

Per Pound.

	Barrels	Smaller Quantities
Concentrated Flux.	4c	5c
Eureka Flux:		
Triple Strength.	8c	3 1/2¢
Extra Concentrated.	4 1/2¢	5c
Crystal.	2c	7c
Gedney's Fluid.	2c	2c
Lennox Fluid.	2c	2c
Perfection Flux.	8c	3 1/2¢ @ 1c
Yager's Salts, 1 lb. bottles.	each, 50¢	
5 lb. bottles, per lb., 45¢		

Soldering Coppers—

Per lb.	22¢@24¢
---------	---------

Spelter—

Western Spelter.	4 1/2¢ @ 4.60¢
------------------	----------------

Spiral Pipe—

See Conductors.

Stove Pipe Elbows—

See Elbows, Stove Pipe.

Stove Trucks—

See Trucks, Stove.

Strainers, Conductor—

Galvanized.	50¢
-------------	-----

Tin Pigs and Bars—

Banca, pigs, 1/2 lb.	34 1/2¢ @ 35¢
Straits, pigs, 1/2 lb.	31¢ @ 34 1/2¢
Straits, in bars, 1/2 lb.	34 1/2¢ @ 35¢

Tin Plates, American

Charcoal Plates, Bright—

N. B.—The price of 20 x 28 sizes is double the price of 14 x 20.

Calland Grade:	
IC, 14 x 20.	\$7.50
IX, 14 x 20.	9.00
IXX, 14 x 20.	10.25
IXXX, 14 x 20.	11.50
IXXXX, 14 x 20.	12.75

Melyn Grade:

IC, 14 x 20.	7.00
IX, 14 x 20.	8.50
IXX, 14 x 20.	9.75
IXXX, 14 x 20.	11.00
IXXXX, 14 x 20.	12.25

Allaway Grade:

IC, 14 x 20.	6.50
IX, 14 x 20.	7.60
IXX, 14 x 20.	8.70
IXXX, 14 x 20.	9.80
IXXXX, 14 x 20.	10.90

Coke Plates, Bright—

Bessemer Steel, or equal to J. B. Grade, full weight	10, 14 x 20.....	\$8.00 @ 1.50
"	IX, 14 x 20.....	\$7.00 @ 7.50

N. B.—The reduction per box on lighter Plates than IC, 14 x 20, is as follows:

100 lb.	15¢
95 lb.	20¢
90 lb.	25¢
85 lb.	30¢

Terne Plates—

N. B.—The following prices are for 10 20 x 28, the rate for 14 x 20 being half as much. IX is usually held at \$2 per box advance for 8 to 10 lb coating and \$2.50 to \$3 advance for 15 lb and upward.

About 40 lb coating.	\$17.50 @ 18.00
About 30 lb coating.	16.75 @ 17.25
About 20 lb coating.	14.75 @ 15.25
About 15 lb coating.	12.75 @ 13.25
About 8 lb coating.	11.50 @ 11.60

Boiler Plates, American—

IXX, 14 x 28..(112 sheets)	\$13.00
IXX, 14 x 28..(112 sheets)	\$14.00
IXX, 14 x 31..(112 sheets)	15.50

Troughs, Eave—

See Eave Trough.

Trucks, Stove—

Improved Look Frame, per doz.	\$15.00
Steel Look Frame, per doz.	16.00
Daisy Improved pattern, 1/2 doz.	16.00

Tubes and Tubing—

Brazen Brass, List Feb. 26, 1896, 30¢@35¢ Copper and Bronze, 3c per lb. list more than Brass.

Seamless Brass Tubes, not list Feb. 6, 1899.

Tin.	20¢
Galvanized.	25¢
Fittings for do.	40¢

Zinc—

600 lb oaks 1/2 lb.	64¢
Per lb.	70¢

PLUMBERS' AND STEAM FITTERS' SUPPLIES.

Boilers, Galvanized—

Standard Boilers:				
30 gal.	65¢@10¢@70¢			
35 and 40 gal.	65¢@65¢@10¢			
Other sizes up to 52 gal.	60¢@80¢@10¢			
52 gal. and above.	60¢@80¢@5¢			
Extra Heavy Boilers:				
18 to 52 gal.	50¢@10¢@60¢			
53 gal. and above.	50¢@55¢			

Brass Work, Plumbers'—

List of December 7, 1896.

Compression:				
Basin Cocks.	85¢@85¢@5¢			
Bath Cocks and Double Bath Cocks.	65¢@70¢			
Bibs.	85¢@85¢@5¢			
Elbs, Flanged.	85¢@70¢			
Fuller:				
Bibs.	70¢@70¢@10¢			
Basin Cocks, Nos. 1 to 4.	70¢@10¢@75¢			
Bath Cocks, No. 4 1/2.	\$2.00 net			
Ground Key Work:				
Finished Bibs.	85¢@70¢			
Rough Bibs and Stops.	70¢@75¢			
Rough Stop and Stop and Waste	70¢@75¢			
Cocks.	70¢@70¢@5¢			
Rough Stop and Stop and Waste	70¢@75¢			
Cocks, Patented.	85¢@85¢@5¢			

Miscellaneous—

Basin Clamps.</

TINSMITHS' HELPER and PATTERN BOOK

WITH USEFUL RULES,
DIAGRAMS and TABLES
= By H. K. VosBurgh =
NEW AND IMPROVED EDITION

A USEFUL handbook for tinsmiths and other mechanics, treating simple problems in pattern cutting, such as are of daily occurrence in the shop.

An elementary manual for the young tinsmiths; A handy reference for all sheet metal workers.

120 Pages
53 Figures

An Invaluable \$1.00
Pocket Companion . .

**Section 1 ~ Pages 1-66
Diagrams and Patterns**

Demonstrates in a simple way, and by means of illustrations and descriptive text, about 50 examples of sheet metal pattern work, such as the method of cutting can breasts, flared tinware, scale scoops, oval boiler covers, lips for measures, elbow patterns, &c.

**Section 2 ~ Pages 69-88
Epitome of Mensuration**

Compiled with regard to the requirements of the tinner, describing how to find the area of a circle, the circumference of a circle, the contents of a sphere, a cylinder, a cone, and other information relating to the work of a tinsmith.

**Section 3 ~ Pages 89-120
Tables, Rules, Recipes**

Gives tables of the weights of sheet metals, including the weight of black sheet iron, sheet lead, and galvanized iron sheets with their dimensions; the weight of lead pipe per foot; the weights of tin plates, sheet copper and sheet zinc. Several pages are devoted to tables giving the areas and circumferences of circles, the capacity of cans, the number of barrels in cisterns and tanks, sizes of tinware in form of frustum of a cone, &c., and practical receipts, including mixtures for solders of different kinds, soldering fluxes, and various cements.

COST	SELL
Analysis No. 72,330. New York, Dec. 7, 1896.	
We have made a careful examination of a sample of "Agate Nickel Steel Ware" received from The	
Lalance & Grosjean Mfg. Co., Nov. 30, 1896.	
The enamel coating is homogeneous, of extra	
thickness, and great purity.	
It is entirely free from arsenic, lead and anti-	
mony—metals so often found in enameled goods.	
Very respectfully,	
STILLWELL & CLAPPING,	
Chemists to the New York Produce Exchange.	
{ Pierre de P. Ricketts, E.M., Ph.D.	
{ John H. Banks, E.M., Ph.D.	
Analysis No. 14,180. New York, May 6, 1897.	
LALANCE & GROSJEAN MFG. CO.:	
GENTLEMEN—As requested by you, we purchased in	
the open market a sample of "Agate Nickel Steel	
Ware" and have made a careful chemical analysis	
of the enamel covering of the same.	
We find this enamel is absolutely pure and free	
from Arsenic, Antimony, Lead and other sub-	
stances injurious to health. We can therefore	
recommend it for all culinary and drinking	
purposes. Respectfully yours,	
RICKETTS & BANKS,	
Chemists to the N. Y. Metal Exchange.

A UNIVERSAL REMEDY FOR LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 800 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails.

Galvanizing and Tinning.

A Practical Treatise on Coating with Tin and Zinc, with a Special Chapter on Tinning Gray Iron Castings. By W. T. Flanders. Size 5½ x 8 inches. 93 pages, 40 illustrations. Cloth bound. Price \$2.00.

The author of this work has made a specialty of galvanizing and tinning, and has been employed to erect plants in various parts of the country, also to instruct the owners, so that, in all instances, they have been able to operate them successfully. The subject of galvanizing is, therefore, treated from the standpoint of an expert and in a practical manner. The selection of materials and apparatus for erecting plants of large and small capacity is treated, together with instructions for their equipment and accompanied by many illustrations of the plants and of the tools and appliances. Plain directions are given for the preparatory treatment of metals and articles to be coated, and every detail which is of importance in successfully applying to metals a secure and attractive coating is described. The tinning of articles is treated in the same practical manner. The difficulties found by many who have attempted to tin malleable and gray iron castings are explained and methods for doing the work made simple.

CONTENTS.

ART In Metal Ceilings. GOTHIC STYLE.

One of the noblest styles of architecture and design is that known as Gothic.

The round arch style originated in France, the pointed arch being a later development.

From France, Gothic was introduced in England and Germany. It became extremely popular for churches, and is, perhaps, the leading one of the accepted styles for that purpose.

For the interior decoration of churches our Gothic design is particularly appropriate. The background is stippled, with stucco effect. The ornamentation is elegant in its simplicity and thoroughly in harmony with the characteristics of this historic style.

Write for details.

THE GARVIN MACHINE CO.,

51 No. 7th St., PHILA., PA. Spring and Varick Sts., NEW YORK.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting as applied to all branches of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection of 218 problems and an elaborate explanation of the principles of pattern cutting, including Triangulation.

It embodies the problems of the former Metal Worker Pattern Book, all of which have been revised, and many of which have been entirely rewritten and solved by more approved methods. To these have been added 75 new problems and much other new material and explanatory matter, making this work a model of completeness in every respect.

ARRANGEMENT.

In point of arrangement the new work far surpasses the former one in that the problems are classified under three different heads, and simply indexed, and also that by means of a table of contents any required department of the work can be easily found.

CONTENTS.

While Chapter VI, comprising the greater part of the work, is devoted to the solution of problems, the five preceding chapters thoroughly explain the principles of pattern cutting, and place the student in possession of the preliminary information necessary to a thorough understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tanners, Cornice Makers and Sheet Metal Workers should be provided with a copy of

The New Metal Worker Pattern Book.

Price \$5, post or expressage paid.

THE ELECTRIC CITY GUTTER FORMER.

The Electric City Gutter Former can be bought for 50 per cent. less than other machines intended for the same purpose. This machine will do everything that can be accomplished by any other gutter former. No other machine can do better work. No other machine can do quicker work.

The principle of this machine is entirely different from any other. It is more practical. Both the bead and the gutter are formed in one continuous operation. You do not waste any time in hard work in getting the body of the gutter in proper shape. Every operation is mechanical. Each length of gutter is formed exactly alike. No other machine is as practical in its operation. No other machine will give as much satisfaction. The low price is very attractive. The machine will perfectly demonstrate our claims.

Ask us about it. We gladly furnish information and price on request.

THE DOUBLE TRUSS CORNICE BRAKE CO., - 1453 Niagara St., BUFFALO, N. Y.

Our Improved Double Truss Cornice Brake is the most practical machine of its kind in the market. Let us send you a description of its merits. Our "latest" has a double edge on front leaf for making fine members and corrugations.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No. 12 gauge, cut wire or bar-steel $\frac{1}{8}$ inch thick, cut off and mitre angle iron $\frac{1}{8}$ inch thick, and do it perfectly.

PRICE, - - \$35.00.

Excelsior Point No. 2.—SHEET FLUE.

Notice that in ranges with divided flues, the back of the oven is not heated,—but with our sheet flue the back of the oven is heated, making five sides of the oven that are heated at the same time. The result is a baking heat of great evenness, and the fire responds much quicker than with a divided flue. You thus save fuel and get better results in an "Excelsior Range," than in any other range.

ROUND OAK- STANDARD of AMERICA

CURTIS GANDY CHICAGO 1908

We have never proven our ability to produce the highest class of stove construction more conclusively than in the *Round Oak Steel Range*. It is a marvel of tight fitting (our "strong hold"), high class material, workmanship and ornamentation.

We are speaking a long way ahead

of next season's trade that you may plan to learn more about it. Its percentage of gain in sales this year beats everything we make except the furnace. It will pay you to take up the *Round Oak Steel Range*.

AMERICAN RADIATOR COMPANY

Lake and Dearborn Streets,
CHICAGO.

DO you want to buy a good Number One, Medium Priced Range that will Roast and Bake with the best of them? If you do then do not be persuaded to buy anything but a

GEM-MILLER

STEEL-PLATE

RANGE

Which are far superior to other so-called first-class Ranges as to Roasting, Baking and Durability that are made.

WITH Improved removable Duplex Grate, Improved Water Back for heating water, Flue Lined with Pure Asbestos Board, New Non-Warping Oven Bottoms, Cold-Handled Gravity Latch, Drop Oven and Feed Door, Patent Double Centers, Regulating Damper, Nickel-Plated Towel Rod. All bright parts Nickeled instead of Polished. Nickel Bands on doors are ventilated to prevent tarnishing, and body of Ranges are highly finished.

Special attention is called to the easy manner of Removing and Replacing the Grates and Grate Frames in these Ranges without interfering with the Water Backs or Linings. Simply by taking out the small bolt and removing the Front Grate the entire Bottom Grate and Frame can be drawn out through the Front Draft Door.

I can hold my hand over my chimney. No waste heat. I use a Rochester Radiator and save half the fuel.

THIS shows the construction of the ROCHESTER (stove-pipe) RADIATOR.

THIS has been advertised extensively for years.

THIS is the one your customers have frequently asked you about.

THIS is built like a steam boiler.

THIS has 9/10 of its radiating surface directly over the hot current, where every square inch of surface is as effective as six at the side.

THIS gives the results that have so surprised those who have used them and induced our patrons to do so much missionary work for us. Your patrons will gladly do it for you, if you give them the opportunity. Get a few started and after that they will almost sell themselves.

NEW ERA RADIATOR

HOT FACTS—of which this is No. 2.

Your customers' satisfaction concerns your future profits. With it, success is assured—without it, failure is impending.

Nothing will cause as much satisfaction as something to make home more comfortable—A New Era Radiator.

Given a certain amount of heat that every stove and furnace wastes, and a New Era will make more of it do double service than any other radiator. It is not a question of better material or nicer finish, although New Eras are perfect in this respect. It is the method of construction. The New Era has UPRIGHT tubes—no other style will do, because horizontal tubes obstruct the heat, instead of distributing it. It is the upright tubes of the New Era that cause such even circulation of heated air that the difference in temperature at the floor and ceiling will not vary 5 degrees.

There is a good profit awaiting every dealer who sells them. Send for particulars.

Furnace Heating.

A Practical and Comprehensive Treatise on Warming Buildings with Hot Air, by William G. Snow, with an Appendix on Furnace Fittings. 170 pages; size, 6 x 9 inches. Cloth bound. Price, \$1.50.

This is the only book that has been brought out which presents a systematic and reliable treatment of the warm air furnace system of heating.

It deals with the various types of furnaces, their construction, proper location and setting, together with furnace fittings, and all matters pertaining to the installation of furnaces and to effective and economical heating by warm air. The subject is discussed for the first time by a competent author possessed of a scientific education and a practical training, who presents positive rules, based on a long experience, for guidance in designing furnace systems for dwellings and other buildings where this popular method is employed. The various details of furnace work are described simply and at such length that the volume will be valuable to all who are in any way interested in the subject. It is recommended to practical furnacemen, to architects, builders and house owners, and to tinnors and plumbers in suburban sections who do furnace work. To all these it will prove a reliable text-book and guide.

PARTIAL SUMMARY OF CONTENTS BY CHAPTERS.

Chapter I.—Furnaces—Is devoted to Furnace Construction—The Relative Proportion of Furnace Parts—Secondary Heating Surface—Economy and Efficiency—Heating Capacity and Exposed Wall Surface—Manufacturers' Ratings of Their Own Productions, etc.

Chapter II.—House Heating—Compares Furnaces and other apparatus, and describes Method of Setting Brick and Portable Furnaces—Location and Area of Cold Air Supply—Cold Air Rooms and Air Filters—Return Ducts and Air Circulation—Size of Hot Air Pipes—Location of Registers, etc.

Chapter III.—The Combination System—Discusses Heating Distant Rooms with Radiators—Balancing the System—Location of Water Heater in Furnace—Capacity of Water Heaters—Size of Radiators, etc.

Chapter IV.—Air—Deals with the Necessity of Ventilation—Water Needed to Moisten Air—Expansion of Air—Velocity of Air in Tubes, etc.

Chapter V.—Heating and Ventilation of Buildings—Considers the Size of Furnaces Required—Fresh Air Room and Supply—Air Circulation—Size of Flues—Use of Stack Heaters—Size of Heating Coils in Vent Flues, etc.

Chapter VI.—Heating of Public Buildings, Churches and Stores—Is given to the Size of Furnaces Required—Grate Surface in Ventilated Buildings—Air Supply—Size of Heating and Ventilating Flues—Size of Stack Heater, etc.

Chapter VII.—Fan-Furnace Combination System—Is devoted to Positive Warm Currents from Fan Systems—Location of Fan and Driving Apparatus—How Good Furnaces are Aided by Fans—Types and Efficiency of Fans—Area of Ducts and Flues, etc.

Chapter VIII.—Temperature Control.

Chapter IX.—Estimate and Contract Blanks.

Chapter X.—Value of Fuels. The Proper Size for Furnace Chimneys—with tables.

APPENDIX.

Furnace Fittings.—A section of 45 pages dealing with the Making of Furnace Casings—Metal Cold Air Boxes—Making Furnace Bonnets and Collars—Making Pipe and Elbows—Register Boxes and Stack Shoes, etc.

SENT, POSTPAID, ON RECEIPT OF PRICE, \$1.50

\$2 50 NET.

That's what Bridget said when the water pipe froze up and the water front burst. If you are called to repair the damage, don't hurry, take your time; look up the old torch, or borrow one; struggle hard to get at least a look at the job before night. If you were ready and had an extra

torch or two you might get as much work as that enterprising Jim Jones does. Jones buys Clayton & Lambert Mfg. Co.'s torches. He says "They will give my money back if I don't like them." Yes, jobbers sell them at factory price, or if you send \$3.00 to Clayton & Lambert Mfg. Co., Detroit, Mich., U. S. A., they will send one by paid express. Do it now. Don't wait till you're frozen.

Trimo Giant**This Chain Pipe Wrench**

has interchangeable jaws. Improved method of holding and releasing chain. No locking. Send for catalog.

TRIMONT MFG. CO., Roxbury, Mass., U.S.A.**Morgan's 20th Century Air and Vacuum Valve**

Is a positive seal against air returning to the radiator. Check being perpetually balanced in water requires no pressure to lift it. A banked fire, with drafts closed, will maintain heat night and day in mild weather. Will save four times its cost in a single season.

For the Consideration of the Stove Trade.

There are increasing evidences of the satisfactory business in stoves which has been done this year. The chances are that the increases shown will surprise many who had been figuring upon droughts, strikes and other deterrents, in addition to the standard complaint that the business "is no good any more." But in estimating the present stove business a distinction has to be made among the various classes of heating and cooking apparatus that are now in use as compared with former periods. A full line of these goods can only be made by a few concerns, and the consequence is that many concerns of long standing find their business growing more limited each year, unless they have been able to keep up with the pace. The variety and assortment of hot air furnaces is rapidly increasing, and no doubt will continue to do so to a much greater extent, from the fact that they can be, and are, made a specialty by people who make furnaces only, and who are sharp competitors for business in their sphere. As for steam and hot water heaters, they have made stoves practically obsolete. Gas stoves, steel ranges, tamale stoves, without counting gasoline and oil stoves, are steadily increasing in use, with the consequence that what was formerly known as "the stove business" has completely changed its character.

While these facts are well understood considerable difference of opinion must prevail regarding the trade, depending upon the assortment of goods a concern may make. The conditions and demands governing the stove trade are growing more sharply defined every year, and both makers and dealers are confronted with the same problem. Manufacturers in various sections who formerly considered themselves safe for life in the possession of their business, but who have failed to keep to the front, now find their business becoming more contracted every year. These are apt to be found complaining that "the trade is all cut to pieces," &c. It does not follow that a large concern has a much more happy future in the stove business than many of the smaller ones. Some of the so-called "small concerns" are, and have been, making excellent goods, and up to the present have been satisfied with their progress. They are usually situated in good local trade centers. They cater to that trade and they get it. This cuts into the territory of many of the larger manufacturers, but there is always a field for the latter to spread out, owing to the greater facilities they possess, as compared with the lesser concerns.

So far as the demand for all kinds of heating and cooking goods is concerned all reports agree that it is good, and no doubt exists that this year will show substantial gains in the sales when the books are finally balanced. What the profits will be can only be determined at the same time. Manufacturers generally realize the necessity of maintaining prices; but there are always some who are unwise enough not to do it. The struggle for business all around is fierce. So it will continue to be, and those who cannot offer goods of the best description and variety will have to follow in the rear as best they can.

The Charleston Exposition.

The opening, on Monday, under favorable auspices, of the South Carolina, Interstate and West Indian Exposition at Charleston, S. C., inaugurated what promises to be a useful and profitable undertaking for the promotion of Southern commerce and industry, particularly in its relation to the West Indian and South American trade. The prime idea of the promoters of the enterprise was the development of this trade, the location of the port of Charleston being peculiarly favorable to the promotion of an important export and import business with the seventy principal West Indian Islands and the east coast ports of South America. The fast growing importance of this field, especially since closer relations have been established with Porto Rico and Cuba, is becoming widely recognized by the business men of this country. The exports from the United States to the West Indies last year were greater than the exports to China, Japan and Asiatic Russia combined, and the quickening of this trade will naturally conduce to the profit not only of the South, but of the entire country. The exposition will also be serviceable in drawing attention to the marked progress that has been made of late in the South, and which is only the beginning of what promises to be a wonderful growth and development in that rich section of the country. No doubt, too, its lighter side will prove highly attractive to the pleasure seeker and tourist, who will be further attracted thither by the genial winter climate of Charleston and the picturesque features of Southern life provided at the fair.

Studying Foreign Business Methods Abroad.

United States Consul Joseph I. Brittain, at Nantes, France, in a recent communication to the State Department, strongly urges the desirability of sending young Americans abroad to acquire a practical business training which will fit them for engaging in foreign trade. The Consul believes that it is just as essential for the American business man to have a knowledge of foreign business methods as for him to be familiar with foreign languages. The plan of sending young men abroad is being followed by European exporters and it has been found to give the best results in the extension of trade in foreign countries. Both our commercial enterprise and progress are acknowledged abroad and we undoubtedly have attained a place in the foremost rank in the commercial world. But the Consul is of the opinion that

we cannot expect to force our crisp and rapid business methods upon the conservative Frenchman. We may gradually convince him of the superiority of our system, but we must in the beginning make certain concessions. Young Americans should, he believes, go to France and obtain employment in some large business establishment for six months, one year, or two years, as the exigencies may require. Salaries are low, but he thinks a good many young Americans could get positions that would at least pay their board, while at the same time they would be obtaining experience of great value. In the city of Nantes, with its 200,000 inhabitants, there is but one man from the United States who is engaged in business, and he is with a retail firm, while a number of young men from Great Britain, Belgium and Switzerland are employed temporarily in the leading importing houses, getting a practical knowledge of the language and of French business methods. The kind of employment that a young man of foreign birth could obtain would be attending to the correspondence from his own country, while at the same time he could study French and obtain an insight into the metric system and French peculiarities in business. This policy is followed by Englishmen, Germans, Frenchmen and others, and there seems to be no good reason why such a successful plan could not be followed by American manufacturers and exporters. It would probably be worth the while of exporting houses to assist in the maintenance of one or two young men while they were abroad. The suggestion is at least worthy of careful consideration.

Success of Instruction by Correspondence.

In a recent celebration of its tenth anniversary the International Correspondence Schools of Scranton, Pa., marked an achievement that is probably unparalleled in educational history. The growth of this now famous institution since its inception as the Correspondence School of Mines in 1891 has been something remarkable. When the schools started no one had any conception of the great success that was to follow the undertaking. In 1891 a small staff of eight persons performed the work that now requires the services of a corps of 2500 people and up to the present time 341,500 students have been enrolled. In other words, the total enrollment membership, with their families, on the basis of five persons to a family, would people a city of nearly two million population. This immense patronage affords a conclusive proof of the fact that the correspondence system of technical education, introduced by the founders of the International Correspondence Schools, has met a wide and distinct need in mechanical and industrial circles, both in this country and abroad, for the operations of the institution now cover Canada and other foreign countries, as well as all the States of the Union. The faith and foresight of its promoters have been abundantly justified by the result. At first the correspondence system of teaching was regarded with considerable skepticism. But as the public became acquainted with the work of the schools and realized the practical results as shown in the success of the students the doubt as to the ability to teach and learn in this way gradually disappeared. Now education by mail is a recognized institution, the efficiency and importance of which is generally admitted. It must be intensely gratifying to the schools to be able to state that thousands of their students are filling important positions in every line of industry and in every quarter of the civilized world. Testimonials show that numbers of their clients have secured higher positions directly through the improve-

ment and advancement in technical knowledge acquired by their correspondence instruction. Many others have been placed in lucrative positions through the agency of the schools. The International Correspondence Schools is an institution which fully merits the support and approval of business men, and all who are interested in the technical and industrial advancement of the country.

Editorial Notes.

We print this week, in another column, a communication from our London correspondent regarding a controversy which has arisen in British tin plate circles regarding the use of the terms "charcoal" and "coke," as applied to tin plates. Under the present methods of manufacture these terms no longer have the significance they originally possessed, all tin plates being made of either Bessemer or Siemens steel. Only a very small portion of the plates now manufactured, either in this country or abroad, are actually made from charcoal iron, although a large proportion of the tin plate product is offered under the name of charcoal plates. The suggestion that in future tin plates should be known either as "Bessemer" or "Siemens" has much to recommend it. It would be an advantage to the trade if these terms were substituted for the old method of nomenclature, for it is admitted that the present way of denominating tin plates is confusing and misleading, and that in many instances coke plates are branded and sold as charcoal. In all departments of trade to-day the tendency is toward the abolition of antique trade terms which have lost their significance and the adoption of new terms which more actually fit the case.

The demand for American anthracite coal in Europe seems to be growing rapidly. So many large foreign orders have been received by the Philadelphia & Reading Coal, Iron & Railroad Company that their capacity to furnish the fuel is becoming overtaxed and they have decided to accept no more foreign business for the present. The strike in the mining districts of France and South Wales, from which places Europe obtains the greater part of its supply of anthracite, has induced many users of hard coal to seek supplies on this side of the water. American consuls on the Continent report the arrival at various European ports of cargoes of anthracite coal, which is delivered at its destination, in many cases at a cheaper rate than the South Wales product can be purchased. For instance, a cargo of anthracite has been delivered in Berlin 49 cents per ton cheaper than the Welsh coal would have cost, and Consul Brittain, at Nantes, France, reports that a leading coal firm in that city had been able to buy American anthracite coal at 50 cents a ton below the cost of Welsh coal, the freight charges on the latter not being taken into consideration. It would appear that a large market for our surplus anthracite product exists in Europe. No doubt American coal operators will take advantage of the opportunity thus opening up.

Postmaster-General Smith, in his annual report, emphasizes the necessity for a rectification by Congress of the abuses which have grown up in connection with the privileges accorded under the present postal law to second class mail matter. Second class matter, the Postmaster-General points out, constitutes nearly three-fifths of the weight of the entire mail of the country, while it pays only one-twenty-eighth part of the postal revenue. As things are at present the Post Office Department is virtually paying a subsidy of \$12,000,000 a year for purely private publishing enterprises. The carrying of this burden prevents the Department from introducing a number of desirable improvements for the postal service which would tend to benefit the public at large.

The Eastern Stove Trade.

Evidently the interest taken in our recent article on the condition of the stove trade in one section of the East has not ceased with the letters presented in our last issue, as a number of further communications referring to the subject have been received. We present below a few more letters from the many which have come to us within the past few days, and trust that the discussion which has been opened up in these columns may result in more harmonious relations in the trade, to the benefit of all alike.

Some of our correspondents, while admitting that our presentation of the conditions was correct, deprecate the fact that it was made at all, taking the position that no benefit could come from giving the stove dealers throughout the country so much information, which, they claim, would be of doubtful interest to the latter. This expression of opinion gives us the opportunity of saying that seldom does any deviation from the rules or agreements of the stove associations remain for any considerable time unknown to the stove dealers, who are found to be men of considerable shrewdness when it comes to the question of being informed as to what is being done by the manufacturers, so as to enable them to buy their stock as cheaply as can competitors who may be looked upon by some manufacturing concerns as worthy of special consideration. Then again, we have the authority of the last Presidential message as to the benefit of publicity for the purpose of protecting general interests.

PRICES TOO LOW IN EASTERN MARKET.

A leading Eastern manufacturer sends us the following:

In a general way, I think what you have said in your article of November 23 is correct touching the Eastern stove trade, and more particularly that of the New York City market and the territory immediately pertaining thereto. Manufacturers located some distance from this territory use it for the purpose of increasing their trade without reference to prices obtained, hoping thus to increase their output and reduce their general ratio of manufacturing expenses. I doubt if any manufacturer could be successful in making money were he to confine himself solely to what would be known as the New York market at present prices.

During the better days of the association which used to meet at the Astor House a general classification of goods and prices was an established fact, and the market was in a comparatively healthy condition. In my opinion, it was broken up by the desire of some manufacturers to increase their output for the purposes above stated. Goods in the New York market, I believe, are being sold at prices at least 10 per cent. less (or even lower) than the same class of goods would bring in the Chicago market; and unless the jealousies which now exist can be smoothed over we must again look, perhaps not for the "survival of the fittest," but the survival of the concern that is willing to make the greatest sacrifices to retain or increase its trade.

ASSOCIATIONS NOT UNQUALIFIEDLY INDORSED.

A manufacturer in the Central West, who, apparently, is not an ardent upholder of the association idea, writes as follows:

Your article on the "Eastern Stove Trade" is timely and in many ways fits the general situation very well. With pig iron and coke rising, steel very scarce and higher in price, and labor independent, we hear of some cases where manufacturers are selling goods at prices that cannot make them a net profit on their business. This, too, at a time when the stove business is good and prices should be very firm or materially advanced.

Up to now our own business exceeds that of any other year, and last month we did the largest business

of any month in our history. We have been and still are very busy, and have not given any attention to association matters. There are always the weak, the mean, the unruly, but a frequent coming together to talk over matters keeps them from becoming worse than they otherwise would be, and this is about as much good as we ever get out of the association business. When it comes to classifying goods and fixing prices it is impossible to suit everybody, and leaks of various kinds are soon discovered, which ends in trouble and the usual row.

ANY ASSOCIATION BETTER THAN NONE.

A representative of one of the larger Western stove manufacturing concerns sends the following interesting communication, in which he registers his approval of associations as a general principle:

I read the recent article in *The Metal Worker*, and by way of comment would say that, to the best of our knowledge, no such conditions as spoken of there exist in the general trade. Of course, you can understand that the Western manufacturers do not come in very close competition, if at all, with Eastern Pennsylvania, New York City and those along the Hudson.

So far as our knowledge goes, the stove trade throughout the West has been in pretty good condition, especially this year. There is, as you undoubtedly know, what is known as the Western Association, which is made up of nearly all the principal stove manufacturers in the West, and they work very harmoniously. Of course, violations are liable to occur in all sorts of associations, unless there is a very heavy forfeit, and even then some members think it is smart to take the chances of not being found out. You know there is an old adage that "You can lock up a thief, but you cannot lock up a liar," and this is the great trouble. When so-called reputable business men agree with their business competitors to do certain things and do not adhere to their agreement, it is sometimes pretty hard to get along.

There exists, as you also undoubtedly know, in New York State the New York State and Northern Pennsylvania Association, which, we understand, works more or less in harmony with what is known as the Pennsylvania Stove Association.

Years ago there existed in the West an association, the agreements of which were very strict, and while there was no forfeit or anything of that kind, this association was very effective. Manufacturers who were members of said association found it very largely to their advantage to adhere to the rules, as they were a great benefit to them.

The net of the whole proposition is that it is a great deal better to associate with a lot of your competitors in such a way that you have some sort of a reasonable knowledge of what they are doing, instead of guessing at it. There are always a lot of so-called business men who seem to think that they are doing good business when they try to cut their prices, with the hope that they will not be found out. Of course, it goes without saying that this sort of thing cannot continue long. Violators of agreements will sooner or later come to grief, and the man who thinks that he can obtain anything but a temporary advantage by cutting his prices is one who, in my opinion, is likely to be badly fooled.

Speaking from an ordinary standpoint, we have always felt that there has been a great benefit derived from almost any kind of associations. Any association is better than none. The associations, as far as our knowledge goes, that exist now do not have any arbitrary rules. They do not attempt to regulate prices or anything of that kind, but simply try to correct ordinary abuses and discuss matters that are of general interest to the trade. Possibly they might be termed as what is commonly known as "a gentlemen's agreement."

A REPORT comes from Pontiac, Mich., that there is a movement on foot for the establishment of a Stove works in that town. It is said that the plans of the promoter include the establishment of a very large works at the South East of the town.

Odin Gas Burners and Heaters.

The Odin Stove Mfg. Company, Erie, Pa., are sending to the trade two circulars that are calculated to attract attention. One, printed on red paper, is devoted to the Tri-Odin three and four way gas burners, designed for use in the fire chambers of cooking stoves. These are made with two burners directly under the cooking holes, and have flames burning from the side, so as to throw a flame against the water front on one side and against the oven on the other, to aid in baking. The company also make circular Tri-Odin burners for use in heating stoves.

The second circular is devoted to the Empire Odin, which is a round gas heating stove made in two sizes, one size having a fire box 15 inches in diameter and standing 50 inches high, and the other a 19-inch fire box and standing 54 inches high. The Empire Odin is spoken of as a strictly pure air gas heater, the fire box being composed entirely of cast iron and having a cast iron tube from 6 to 10 inches in diameter extending from the bottom to the top of the stove, forming a central flue for heating and circulating the air. This air may be taken from the floor of the room or fresh air may be supplied from out of doors. The heater is attractive in appearance, having the fire chamber inclosed in a large illuminating chamber with mica doors all around. The Odin incandescent fuel is placed in the fire chamber and adds to the cheerful effect. The products of combustion, after leaving the fire chamber, pass through a drum and circulate around it five times before they escape to the flue pipe connection near the top of the stove.

Some New Garlands.

Some very pretty circulars which are being sent out by the Michigan Stove Company call attention to the merits of the new Champion-Garland range, intended for using hard coal or wood as a fuel, and to the Sunlight-Garland, a medium priced base burner for anthracite coal. The latter construction is referred to as being entirely new and as the first of the kind ever put upon the market. It is a sheet steel base burner with internal construction similar to the company's well known Art-Garland line, which insures satisfactory operation. Reference is made to the generally admitted fact that sheet iron radiates heat much quicker than cast iron, thus insuring a vast amount of heat with the use of a moderate amount of fuel. The Sunlight-Garland has large fire pot, anti-clinker and center dumping grate, the same as used in the regular Garland line; heavy fire pot and hot air circulating flues, which take the cold air from the floor and discharge it from the top in a highly heated condition.

The new Champion-Garland range is a 6-hole construction with oval shaped fire box, with no corners to become clogged with ashes and impede the draft; aerated oven; direct draft damper under the pipe; extra large pull-out; smooth, solid hearth; capacious ash pan; ventilated Boston ring covers; large broiling door and interchangeable reservoir. The stove is rich in ornamentation and of substantial appearance. All parts are ground and fitted true, giving tight joints and thick plates, thus permitting expansion and contraction with no danger of cracking.

Charles C. Heath & Co.'s Philadelphia Branch.

Chas. C. Heath & Co., manufacturers of and dealers in stoves, ranges, furnaces and supplies, Baltimore and Philadelphia, have leased for a term of years the Colburn Building, 136 and 138 North Second street, Philadelphia, Pa., and will occupy it on January 1 as their Philadelphia branch store, removing at the time from their present location, 63 North Second street. The new building is of brick, five stories high, with 54 feet of frontage on Second street and 70 feet deep. Electric elevators and other conveniences are being installed, and the whole building and its appointments will be modern in every detail. The fourth and fifth floors, we are ad-

vised, will be used as a casting storage department, in connection with a general stove repair trade. Castings of all the Pennsylvania, Maryland and New York makes of stoves are to be kept on hand. The third floor will be used as a shop for the manufacture of furnace castings, hot air pipes and necessary appliances for the general trade. The first and second floors will be devoted to display and sample rooms for the various lines of summer and winter goods. Offices, both general and private, are provided at the rear of the first floor, and the basement is large enough for the storage of ten carloads of stoves. Chas. C. Heath is expected to divide his time between the two stores, and the Philadelphia branch will continue under the management of Henry Swartz.

The company advise us that they will be represented next year by Samuel Snyder, James Kirkland, Cyrus Hatfield and Irving Riggs, who will look after the trade in Maryland, Delaware, Virginia, Pennsylvania, New Jersey and New York.

Death of John F. Mills.

On December 6, at his residence in Port Chester, N. Y., John F. Mills died at the age of 58 years, from abscess of the liver, after a short illness, although his health had not been good for several years. Mr. Mills was a native of Jersey City, N. J., and at the time of his death the vice-president of the stove, boiler and plumbing goods manufacturing house of Abendroth Bros. of New York and Port Chester. As a young man he was a bank clerk in Port Chester, but entered the employ of the Abendroth firm, of which he became a confidential agent and rose to the vice-presidency. He was vice-president of the Port Chester Savings Bank, a warden of St. Peter's Episcopal Church, a member of the village Board of Trustees and of the Harry Howard Hook and Ladder Company. He was also prominent in Masonic circles. In early life Mr. Mills married the daughter of W. P. Abendroth, his wife dying about two years ago. He is survived by four sons.

ODD PLATES.

THE CHARTER OAK STOVE & RANGE COMPANY, St. Louis, Mo., have issued a letter to their friends in the trade calling attention to some very interesting statistics in the way of Stove production. Among other things they state that in the year 1900 they made and shipped more Stoves and Ranges than did their predecessors for a corresponding period, and that up to November 1 they made and shipped more Stoves than during the 12 months of 1900. Up to November 15 they report a gain, as compared with the same period in 1900, of 398 Stoves and Ranges. Unfilled orders now on their files, and those which they can reasonably expect to receive before the close of the year, will, they claim, make their shipments for 1900 reach a grand total of 75,000 Stoves and Ranges. The company express the hope that with increased facilities and advance preparations they will be able next year to give their customers a service more prompt than ever before.

THE ECONOMY FURNACE COMPANY of Cedar Rapids, Iowa, are distributing a 16-page folder in the interest of their Divided Flame Type and Continuous Flame Type of Hot Air Furnaces, which are made in a variety of sizes, some having two tubes run through the combustion chamber to increase the heating surface. The construction all tends to secure a long fire travel and an economical consumption of fuel, at the same time presenting a large amount of heating surface with which the air must come in contact in passing through the Furnace. Six pages are devoted to a series of testimonial letters from those who have used the Furnaces in schools, churches, hospitals, business houses and residences.

"HAVE A LOOK INSIDE," is the inscription on the front and back pages of a four-page folder issued by F. M. Borden & Brother, Philadelphia. The circular calls attention to the fact that the firm are already arranging to present an attractive line of rapid selling goods to

dealers for the coming year, and announces that their catalogue and salesmen will be ready to start visiting them on January 2, 1902. Their line includes Wickless Oil Stoves, Gasoline Stoves, Yellow Flame Stoves, Ovens and Refrigerators.

THE WEIR STOVE COMPANY, Taunton, Mass., had stored at the commencement of the fall trade 6000 Stoves of all kinds, besides their Furnaces. Since then they have been running 75 Stoves and 16 Ranges per day, and up to Saturday last were 200 behind on orders.

"DICK" WARNER of the Stove firm of White, Warner Company, Taunton, Mass., was, on Tuesday, elected Mayor of Taunton by a handsome majority.

WE are informed that the Simpson Stove & Mfg. Company, who will remove their present works from Pittsburgh to Canonsburg, Pa., have drawn plans for a building, 200 x 100 feet, to contain a machine shop among equipment, warerooms and offices. Also a foundry building, 150 x 75 feet, and several small buildings. The plant will be equipped with modern appliances throughout, and is expected to be ready for operation in April or May of next year. The concern are in the market for foundry equipment and gas engines that will develop 100 horse-power. The concern are manufacturers of Gas Ranges and Gas Appliances.

THROUGH the courtesy of President W. G. Withers and Secretary W. F. Habicht of the Pennsylvania Stove Salesmen's Association, *The Metal Worker* is invited to participate in their annual banquet, which will be given in the banqueting room of the Philadelphia Bourse, on Wednesday evening, December 18, when it is expected that a full attendance of the members will be present.

A LARGE sized mailing card is being sent out by the Michigan Stove Company, in which they ask their customers to take time to go carefully over their catalogue and price-list and see if they cannot make up an order for at least samples of some of the Garland productions.

GROUND has been broken for an extension to the Abram Cox Stove Works at Lausdale, Pa.

W. H. COLEBROOK, SONS & Co., Syracuse, N. Y., are sending to the trade a card to which is attached a miniature pipe, with the suggestion, "Put this in your pipe and smoke it." There is a verse about the pipe, but which bears more particularly upon Colebrook's Asbestos Furnace Cement and Stove Putty. The card also gives the address of the Charles Smith Company, 123 Lake street, Chicago, Ill., as the company's Western selling agents, and H. A. Graubery & Co., 413 Central avenue, as their Cincinnati, Ohio, selling agents.

THE "Be Wise" trade-mark of the Gobeille Pattern Company of Cleveland, Ohio, appears embossed in gilt at the top of a card printed in old English type, with the words: "We design and make Patterns for Stoves and Ranges, simple and cheap to manufacture, quietly elegant in appearance. We request your consideration."

WE are advised by the H. Adler Company, Pittsburgh, Pa., that they have engaged M. J. Weldon, formerly with the Pittsburgh Stove & Range Company, to represent their interests in Western New York, Ohio and Indiana.

THE UNION STOVE REPAIR COMPANY, 2852 and 2854 Archer avenue, Chicago, Ill., are sending out leaflets advertising their King brand of Stove Putty for cementing joints in Stoves and Furnaces, and their King brand of Asbestos Furnace Cement. This Cement is composed of asbestos materials and is claimed to be fire and acid proof. It is recommended for the mounting and cementing of joints and seams in Furnaces, Heaters, Ranges and Stoves, making them gas tight. The Cement is claimed to harden quickly and adhere firmly to anything. It is odorless and contains no oil.

THE TURNER BRASS WORKS, Chicago, Ill., are issuing circulars describing the Turner Vapor Lamp, and giving *fac-simile* testimonials from parties in different sections of the country who have used the Lamps with satisfaction. One of the circulars presents a view of the company's new factory building, with its 56,000 square feet of floor space.

Washington Hardware Association.

As noted in the report of the annual meeting of the Western Washington Hardware Association in our last issue, it was decided to enlarge the scope of the organization, and the name was changed to that of the Washington Hardware Association. While this was designated as the third annual meeting of the association, the term is somewhat misleading, as the organization is but 18 months in existence, the first convention having been held on April 19, and the second convention on November 14, 1900. At the meeting held a year ago the secretary reported that they had doubled their membership in seven months, and expressed the hope that they would double it again during 1901. This they failed to do, the membership being increased by 12, making the total 47 at the time of the recent meeting. This, however, was regarded as a very healthy growth for an 18 months old organization, as there are less than 90 Hardware merchants in Western Washington, so that more than half of them have already affiliated with the association.

Mr. Reckers, the secretary, in his annual report referred to the good work done through the local organizations in Seattle and Tacoma in the matter of price agreements and overcoming trade abuses. The local jobbers were ready to pledge themselves to give the smaller towns the same support as they had the merchants in the two larger cities, if local organizations were formed.

Mr. Mohr, in his presidential address, referred to the great object of the association as to cultivate a more fraternal feeling and hearty co-operation among Hardware merchants. He said that when merchants act upon the theory that their competitors are as honest as themselves and have the same lofty purposes in view, they will have learned a valuable lesson. He desired to impress every merchant in the State with the importance of association work as he felt it, and expressed the hope that the day would soon come when all, or nearly all, of the legitimate Hardwaremen of Washington would be affiliated with the association.

Chicago Retail Hardware Association.

At the last regular meeting of the Chicago Retail Hardware Association the Buying Committee reported the quotations they had received on Wire Cloth, Wire Goods, Garden Hose, Gasoline Stoves, &c., and estimates were given by the members present as to the quantities of these goods they would require to meet their wants for the coming season.

In the November issue of the "Bulletin" published by the association, under the heading of "Grievances," appears the following:

We have been having some correspondence with the _____ with regard to their alleged selling direct to consumers. The matter will be fully entered into at our coming meeting. We earnestly hope that this matter may be adjusted satisfactorily to all parties concerned, as it is not the policy of this association to treat any wholesale house that will give us as retail Hardware merchants fair treatment other than in a friendly manner.

Our Grievance Committee has in hand a complaint by one of our members against one of the jobbing houses of this city for persistently selling to our members' customers. If we as retailers expect to continue doing the retail Hardware business of Chicago it will be necessary to oppose this custom of the several Hardware jobbers and manufacturers attending to this retail business for us.

Some years ago some of the wholesale houses occasionally nibbled at an order from a consumer—cautiously of course. This branch of their trade has been spreading out much more than most of us realize. It will not do to ignore this condition of affairs and some step on our part is absolutely necessary. The longer we postpone this action just so much harder the problem will be. We are receiving the excuse from offending parties that they are doing a retail business, not because they like it, but because the other jobbers are retailing. Now we all know that this is not the fact, and we should not entertain such an argument for a moment.

Under the head of "State Association Notes" is the following reference to a complaint which is awaiting adjustment:

The Investigating Committee of the Illinois Retail Hardware Dealers' Association has in process of adjustment a complaint made by one of the members residing in Springfield. This Springfield member had purchased Gasoline Stoves for several years past, and claims that he purchased his line this year on the same terms as he had done in the past—that is, that he had been the exclusive agent in Springfield for that line of goods. He also claims that the manufacturer sold a large bill of the same class of goods under the same name to a department store in Springfield, after having taken complainant's order. Furthermore, that the offending party sold the goods at a much lower price to the department store. Furthermore, that the party offending refused to adjust the matter in any way. Later on the complainant requested permission to return his Stoves or to be made a rebate on his Stoves, placing him in a position to meet the competition of the department store. All of these requests were steadfastly refused, the manufacturer insisting on payment of his Stoves at prices agreed upon when the goods were purchased, the manufacturer also maintaining that he had made no agreement as to exclusive agency with the retailer making the complaint. Final adjustment of this matter will probably not be made until the next annual meeting of the Illinois Association, when both sides should be heard so that all of the facts may be brought out satisfactorily, &c.

Indiana Retail Hardware Dealers' Association.

M. L. Corey, Argos, Ind., secretary and treasurer of the Indiana Retail Hardware Dealers' Association, has issued the following circular under date November 30, in which announcement is made of the time and place of the next annual meeting, together with some remarks concerning the work of the association and what has been accomplished through its efforts:

The next meeting of the Indiana Retail Hardware Dealers' Association will be held in Indianapolis, February 19 and 20, 1902. Headquarters at the Hotel Denison. This meeting promises to be the best and largest in our history. We expect to profit by past experience in arranging programme and discussions to the extent that no dealer who is progressive can afford to stay away. The social feature will not be neglected, but this year the entertaining will be done by the association without asking outside aid.

We have received about 50 applications recently, and the feeling expressed by dealers of our State who are not yet members shows they are interested and appreciate our efforts. We ask every one expecting to attend and join us at our meeting to write the secretary at once, so that proper arrangements can be made.

Quite a number of complaints have been filed this term, but nearly all have been satisfactorily adjusted. Present conditions show more harmony between jobbers and dealers than heretofore. Jobbers are respecting our rights and grounds (with a very few exceptions), and find they gain by adopting this course.

Some trade papers claim that dealers are buying more from manufacturers direct than heretofore. This may be true in some places, but the contrary generally prevails. Some goods (specialties particularly) always will be bought direct from manufacturers, because as a rule jobbers cannot guarantee an exclusive vicinity sale contract. The jobber that caters to dealers only, and is not enjoying a good business, must look for some other cause for the difficulty.

There are still a few jobbers who do not deserve our patronage. Their course demoralizes our business, and encourages undue and illegitimate competition. They solicit the jeweler, druggist, grocer, department store, mill man, blacksmith, lumberman, contractor and even the consumer, and then expect the retail dealer to buy of them. A more absurd proposition would be hard to name, yet some dealers patronize them knowing the conditions.

Again, we have a class of so-called wholesale and retail people who use jobbers' rating in obtaining lower prices, abusing the privilege to dispose of surplus stock. Very often the latter class are our worst price cutters. When the consumer states he

wants to see "Jones before he buys" their regular statement is, "He can't sell at this figure; why he buys of us." The Lindsay Hardware Company recently announced their policy in a booklet sent out to the trade. They say: "We will not sell to contractors, blacksmiths or consumers of any kind under any circumstances. We do not try to get your customers, but will rather help you to keep them. We do everything we possibly can to protect the retailer. We do a wholesale business, nothing else." This statement every association member must approve.

We believe there is a more general disposition to act fairly—to sell better goods on a profitable basis, to assist each other in supplying the entire wants of the consumer instead of allowing this trade to go to mail order houses or bogus bargain leader concerns. There is a more friendly feeling and better understanding between competitors than ever existed before, and we welcome and encourage it all, for to this end associated effort has been directed.

CHRISTMAS IN THE STOVE AND TIN SHOP.

BY SUGGESTION.

With the permission of the editor I would like to give a hint to men who run the smaller stove and tin shops throughout the country, which may help them to get a little more profit out of the approaching holiday season. There is no reason why young America should not make the tin shop as much talked of as some of the other toy stores at this time of the year, if the proprietor is only enterprising enough to cater to their amusement and not consider it a bother to give the youngsters the attention which they need.

The old folks may not be delighted with the fact that Christmas, like the Fourth of July, is most enjoyed when accompanied by considerable noise. To the stove and tin shop belongs the right to sell the penny tin whistles and tin fifes, to say nothing about the tin horns of various sizes, which are made use of during the holiday season and for ushering in the new year. I would suggest trimming the window for the benefit of the little fellows. The proprietor can easily get a large card and paste on strips of red and blue paper across one-third of the card at each end, so as to make stripes of red, white and blue. On this card he should fasten, in the shape of a star, appropriate for the Christmas season, small, round tin whistles with a hole through the center, with the price conspicuously marked. If he then hangs penny trumpets, 5-centers, tin horns and "grandad" horns all around the card and window he will only have occasion to open his store door when school lets out and blow a few blasts on a "grandad" horn to attract attention to his show window. Now this part is purely for the benefit of the youngsters; but, if he has any of the Yankee shrewdness, which every American ought to possess, he will ask the youngsters who come in if they do not need at home a new pudding pan, sauce pan, dripping pan, parlor stove, or some other thing, while he is making a sale to them.

It will be unpardonable neglect if he does not have for the little girls, who are sure to watch the boys, some little dust pans, patty pans, teakettles, doll wash basins and such things as will add to the pleasure of their acquaintance with the shop and that will contribute much to their solid comfort when they become real housekeepers. Such stock costs very little, and the sale of it, even with little or no profit, will be a big advertisement. If he has any pretty little circulars of parlor stoves, kitchen ranges, or a special Christmas circular devoted to other goods to distribute when he is making these sales he will find that there is profit in paying some attention to a branch of Christmas trade that may have heretofore escaped his notice.

I make this suggestion because I know that many stove men get into the habit of thinking that the business of the year is pretty well over at this season and do not make any considerable specialty of catering for Christmas trade. Many men make a commendable use of their time in getting their books into shape and the bills made out for the first of the year. This they ought to do, for the sooner the bills are out and distributed the more likely they are to be paid. Instead of the holi-

day season being a dull time for trade the man in business for himself ought to be working double time in his business, besides putting in a little extra time for the benefit of his family. He will find an increased enjoyment in the extra time if the period spent in taking care of his business and getting his bills out is utilized industriously, intelligently and by all means in a happy frame of mind, so as to make all who come in contact with him feel that there is some pleasure in his acquaintance, even if he does present a bill for the old account, long overdue.

The National Enameling & Stamping Company's Fire.

The fire on the night of the 27th ult. which totally destroyed the entire plant of the National Enameling & Stamping Company, located on the site bounded by Metropolitan, Bedford and Driggs avenues and North First street, Brooklyn, N. Y., will not embarrass the company in executing orders for goods. The trade sending in orders the day after Thanksgiving were not delayed 24 hours in shipments, we are advised, owing to the proximity of their two plants, one on North Third street, nearby, and the Berlin Works at Laurel Hill, Long Island, a suburb of Brooklyn, aside from other comparatively nearby factories at Portland, Conn., and Baltimore, Md., from which to draw. The destruction was total, the loss, however, being fully covered by insurance. How the fire occurred is not known, the gray haired watchman, with his lantern over his arm and accompanied by his dog, being found in the ruins burned so as to be almost unrecognizable. Whether or not the works will be rebuilt on the old site has not been determined.

The Star Enameling & Stamping Company.

In a letter received from C. E. Christman, president of the reorganized Star Enameling & Stamping Company of Pittsburgh, Pa., he informs us that he and his associates have purchased from the Pennsylvania Trust Company, receivers for the old concern, successors to the Star Dinner Pail Company, all of the company's assets, except the book accounts. They have been incorporated under the laws of New Jersey with a capital stock of \$100,000. A directors' meeting was held recently at the offices of the company in Allegheny, Pa., when the following officers were elected: President and general manager, C. E. Christman; vice-president, J. Roth; treasurer, A. F. Loch; secretary, George W. Rowbottom, Jr. The new company are arranging to give the plant a modern equipment, which will largely increase its facilities. The factory was put in operation on November 18, and the demand for their goods has been so large that it has been necessary to run a day and a night shift of hands. The company's plant will remain at its present location in Allegheny, there being no truth in the report that it will be removed to McKeesport.

Stove and Hardware Dealers.

HIBBARD HARDWARE COMPANY have succeeded C. B. Cruwell & Co., in the Hardware, Stove, Tinware and Sporting Goods business in Oskaloosa, Iowa. The new firm have made a number of improvements in the establishment, including new front and shelving.

S. B. COLVIN has succeeded Colvin & Mechling, dealers in Hardware, Stoves, Farm Implements, &c., Mt. Pleasant, Pa.

LOCKWOOD & PALMER, Stamford, Conn., are erecting a modern three-story brick and iron building, 66½ x 85 feet, all of which they will devote to their business of Hardware, Stoves and House Furnishing Goods. The building will be up to date in all its appointments, and they expect to take possession about January 1.

HINES & VOPALENSKY is the style of a new Hardware firm at Morse Bluff, Neb. They are dealers in Shelf and Heavy Hardware, Stoves, Tinware and Sporting Goods, of which a good stock is carried.

MITCHELL & TRIMBLE have recently engaged in business in Apache, O. T., handling Shelf Hardware, Tinware, Stoves, Farm Implements, Harness, &c. They occupy a building 24 x 80 feet and have a warehouse, 24 x 40 feet, in course of erection.

DEVANEY & SON are a new firm in Cascade, Iowa, carrying a line embracing Shelf and Heavy Hardware, Tinware, Sporting Goods, &c. They make a specialty of Furnace work and plumbing.

E. T. SMITH HARDWARE & FURNITURE COMPANY, Arcadia, Fla., have lately incorporated with a capital stock of \$50,000, to carry on the wholesale and retail business in Shelf and Heavy Hardware, Stoves, Tinware, Agricultural Implements, Sporting Goods, furniture, &c. The company have recently completed quite a large addition to their former establishment.

BALDWIN REFRIGERATOR COMPANY, Burlington, Vt., have published a new catalogue showing the Baldwin line of Refrigerators for 1902. The company state that they manufacture about 140 styles and sizes in hard wood and soft wood, metal, porcelain and spruce lined.

J. C. SHANNON & SON, who have conducted a general Hardware, Plumbing and Seed store in Penn Yan, N. Y., for many years, have disposed of their Hardware and Plumbing business to Peck & Co., who have Hardware stores in Corning, Bath, Plattsburg and other places, making a total of seven stores under their management. Peck & Co. will take possession of the Penn Yan store about the middle of January.

WE take pleasure in acknowledging the receipt of an invitation to attend the second annual banquet of the San Francisco and Oakland Retail Hardware Dealers' Association, to be held at the Maison Tortoni, San Francisco, on Friday, December 6. The association has arranged to bring together at this banquet as many as possible of the local Hardware merchants, both jobbers and retailers, and an interesting and enjoyable evening is looked for.

THE HUMPHREYS-DAVIDSON HARDWARE COMPANY, Wytheville, Va., will open about January 1 an up to date Hardware store. They will carry in stock a full line of Shelf and Heavy Hardware, also Stoves and Agricultural Implements. The officers of the company are as follows: M. H. Davidson, late of Roanoke, president; H. O. Humphreys, late of Bedford City, vice-president; W. S. Humphreys, late of Bedford City, secretary and treasurer.

REFERENCE was made in our last issue to a conference called by the Monongahela Valley Retail Hardware Dealers' Association, to which the Hardware merchants of that State have been invited. We are, however, advised by J. F. Frye, Charleroi, Pa., secretary of the association, that the date of the meeting has been changed to Thursday, December 12. The Monongahela House, Pittsburgh, will be the scene of the gathering.

C. F. MYERS has succeeded to the business formerly conducted under the style of E. J. Post & Co., Albuquerque, N. M. Mr. Myers clerked for 12 years for a Hardware house in St. Louis before coming to Albuquerque, and entered the employ of E. J. Post & Co. in 1889. He was admitted to an interest in the firm on January 1, 1891. Since 1894 Mr. Myers has had full charge of the business, Mr. Post having retired from active participation. A wholesale and retail trade is done, principally wholesale, in Hardware, Shelf and Heavy, Stoves, Tinware, Farming Implements, Sporting Goods, &c.

LEE & POLLOCK have purchased the Hardware, Stove, Farm Implement, Harness, Buggy and Wagon business of A. F. Schofield, Collinsville, Ind. Ter., and will continue at the old stand.

M. J. SHOWERS has lately embarked in business in Apache, Oklahoma. His line comprises Shelf and Heavy Hardware, Stoves and Tinware, Sporting Goods, &c.

THE Executive Committee of the Illinois Retail Hardware Dealers' Association will meet in Decatur at an early date to make final arrangements for the annual meeting, to be held some time in February next.

The Waukesha Sheet Steel Company

Illustrations are presented herewith of the new sheet steel works of the Waukesha Sheet Steel Company, located at Waukesha, Wis. Instead of investing considerable capital in the erection of the necessary buildings the company leased the buildings formerly used as repair shops and recently vacated by the Wisconsin Central Railway Company. The buildings were admirably adapted for the purpose to which they have been put, requiring but slight alterations and additions. The latest developments in sheet rolling practice were adopted in the selection of machinery and other equipment, so that the works can be referred to as a thoroughly modern six-mill plant, with all that is necessary for turning out from 75 to 100 tons of steel sheets daily. The company will manufacture steel sheets, black and galvanized, plain and painted, flat and corrugated.

The main building is 120 x 375 feet, constructed of

plunger pumps. The entire equipment is automatically arranged and everything necessary for decreasing the cost of operations has been introduced.

The machine shop is housed in a brick building 40 x 60 feet, with slate roof, and is thoroughly equipped with all necessary modern tools, including drills, planers, lathes, &c., all of which are operated by electric motor. A blacksmith shop adjoins the machine shop.

The electrical equipment is furnished by the Northern Electric Company of Madison, Wis., and consists of one 150-kw. dynamo, driven by a Brown-Corliss 20 x 40 inch 250 horse-power engine. Steam is furnished for this equipment by a special battery of boilers. The dynamo furnishes power to operate all the machinery in the plant with the exception of that operated from the main engine. The building containing the electrical power plant is of brick, 60 x 150 feet.

The galvanizing department occupies a brick building 80 x 240 feet. In addition to the galvanizing tanks

Fig. 1.—The Waukesha Sheet Steel Company.

brick throughout, and has a steel trussed roof covered with slate. This building contains six hot mills, two cold mills and one 24-inch bar mill. The hot mills comprise three 26, one 28, one 30 and one 32 inch. A 1500 horse-power 30 x 60 inch engine, having an 80-ton fly wheel, is installed in this building to operate the mills, as well as sufficient finishing shears for squaring the sheets and bar mill shears for cutting the bars to the proper length. All the shears are operated by electric motors. A 15-ton electric traveling crane, having a 60-foot span, built by Pawling & Harnischfeger, Milwaukee, Wis., traverses a runway over the engine, roll trains, &c. A 60 x 300 foot lean-to, which adjoins the building, contains two bar mill heating furnaces, six sheet and pair furnaces and two double annealing furnaces.

The boiler house is a brick structure, 90 x 100 feet, equipped with Lynn type vertical water tube boilers, manufactured by the Tudor Boiler Mfg. Company, Cincinnati, Ohio. This battery of boilers is operated by automatic stokers, made and installed by the Green Engineering Company of Chicago, Ill. The feed water and purifier is operated by a Cookson heater, made by the Bates Machine Company of Joliet, Ill. The boiler house also contains two large size Deane outside packed

this building contains the shipping room. Another building is the stock house, 100 x 160 feet. Switches from the Wisconsin Central Railway run into the plant, and ample track facilities are provided for loading and unloading as many cars as may be required.

The company have completed arrangements to install two 50-ton basic open hearth furnaces, as well as a puddling department, to furnish their steel and iron bars.

A two-story building, 50 x 60 feet, is in process of erection, which will be used for office purposes. The officers of the company are: President, F. J. Patterson; vice-president and general manager, J. E. Jones; secretary and treasurer, Geo. Firmenich. The company also maintain an office in Chicago, located in room 1403, Masonic Temple.

THE CURTIS STEEL SHEET & CORRUGATING COMPANY, Zanesville, Ohio, will have two more Sheet mills completed and in operation before the end of the year, which, in addition to the two mills recently started will give them a four-mill plant. The company removed the Curtis Steel Roofing Company's plant from Niles to Zanesville, and will use the bulk of the product of their Sheet mills in their corrugating department.

A BRITISH TIN PLATE CONTROVERSY.

[FROM OUR LONDON CORRESPONDENT.]

LONDON, November 26, 1901.—A controversy of some importance to the tin plate trade in the United Kingdom has been started by a prominent Birmingham merchant, T. W. Petersen. At a recent meeting of the Birmingham Chamber of Commerce he explained that years ago there were two kinds of tin plate made and exported from this country. These were known as coke plates and charcoal plates from the process of manufacture. They were then made of iron, but now the denominations are absolutely misleading, because they are now made of Bessemer or Siemens-Martin steel, thinly or thickly coated with tin, according to the quality. The mischief that is now being done lies in the fact that, in

quote for what are known as genuine charcoal plates, when, we need hardly say, we lose all orders, as some of our competitors lend themselves to the above practices, which we will not countenance. We certainly think that the Chambers of Commerce are the right and proper parties to take this matter up, and we think the only way to decide the matter is to designate the plates as either Bessemer or Siemens-Martin tin plates, and that, where an extra tinning is required, the plates should be sold upon the sample, as, of course, there are endless thicknesses of tin coating, which makes it impossible to represent the plates under the terms "coke" and "charcoal." There are dozens of kinds of so-called cokes, and still more of charcoal, all different in appearance, either from the mode of manufacture or the thickness of the tin on the plates. We find, as a rule, that those who sell so-called cheap charcoal plates do not charge more than 1 shilling 3 pence to 1 shilling 6 pence per box over coke price. But, of course, you can go

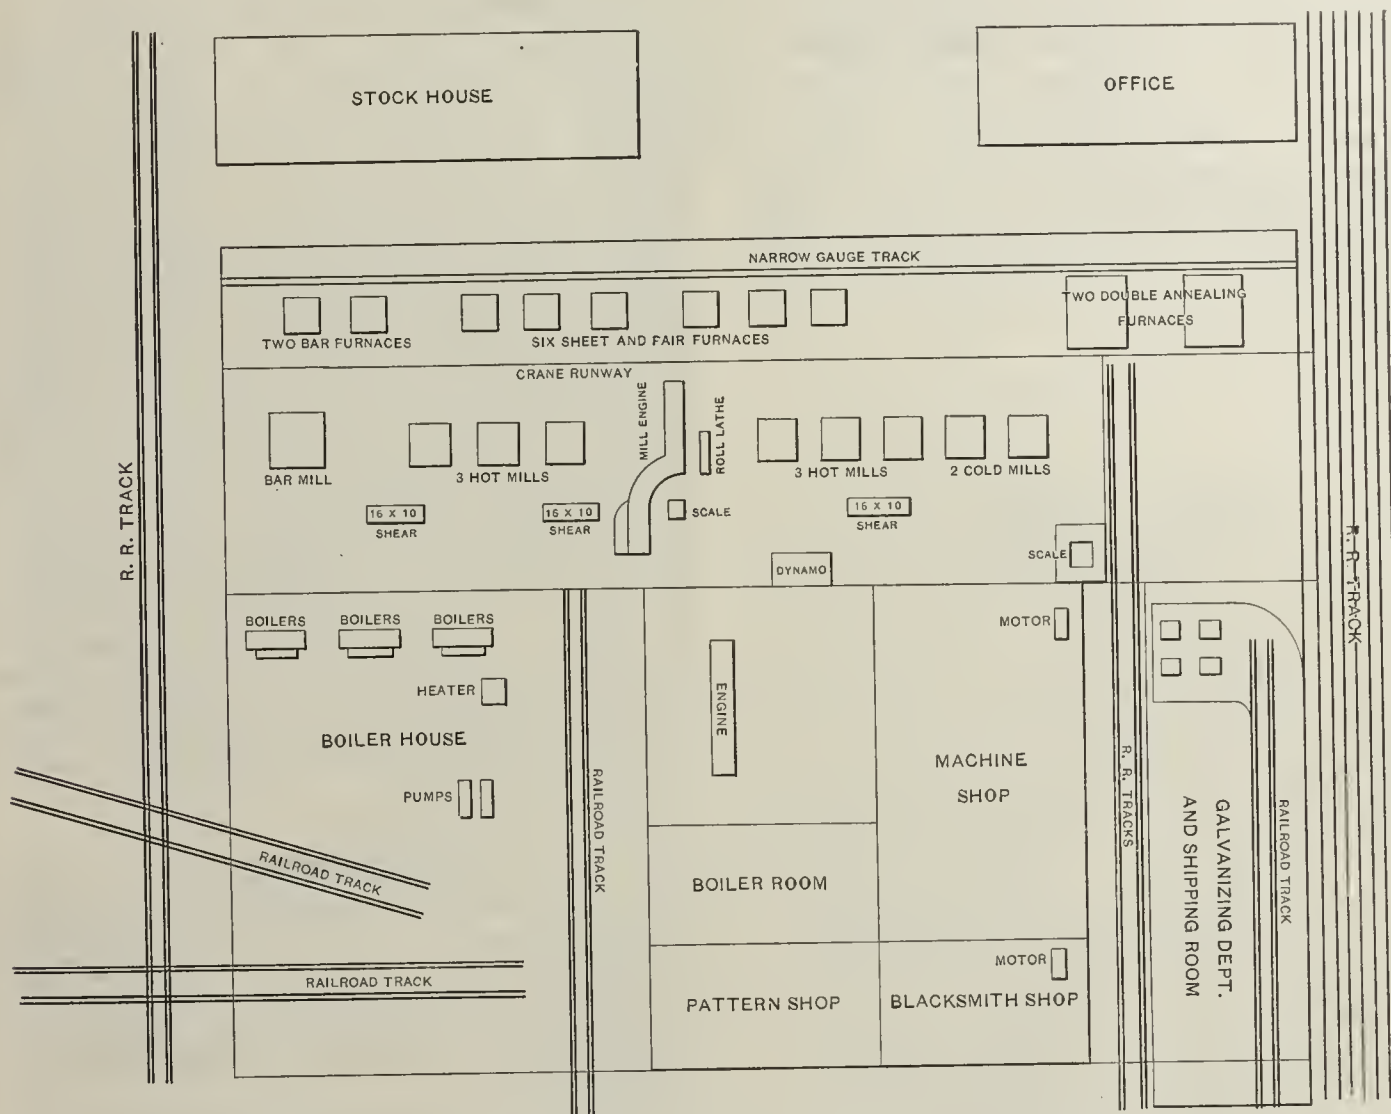

Fig. 2.—Ground Plan.

foreign countries, unprincipled dealers sell under the denomination "charcoal" common steel plates, which are heavily coated, and thereby mislead the buyers. In reply to inquiries from foreign countries, English manufacturers have quoted for Siemens-Martin, and then came a competitor who quoted for common plates made of Bessemer steel, which were heavier coated, and the former were undersold. His contention was that the denomination of "charcoal" or "coke" ought to be altered to Bessemer or Siemens-Martin.

It was decided to communicate with the Newport, Cardiff and Swansea Chambers of Commerce with reference to Mr. Petersen's final suggestion. Serious objection, however, has been taken in certain quarters to Mr. Petersen's charge, which really amounts to one of false description. Mr. Petersen, however, seems to have fortified himself with the opinions of his fellow merchants. For example, a London broker writes to him as follows:

As a matter of principle, we entirely agree with you. We may add that we ourselves are occasionally asked for coke tin plates to be marked charcoal; but, as we never lend ourselves to these practices, we simply

considerably higher, the quantity of tin governing the price. The quantity of tin put on ordinary coke plates is about 2½ pounds per box, for common charcoal about 3½ pounds. There is not the slightest doubt that the introduction of steel has entirely upset the tin plate trade, and the honest dealer or merchant is entirely knocked out of it, unless he can sell his plates upon sample. We will endeavor to take the matter up with some leading parties interested in the trade, and if we can help the matter forward further, it will give us much pleasure.

This London firm are certainly in earnest in the matter, for they have gone further and consulted their fellow merchants, with the result that in a later letter they write as follows:

We have brought the matter before the Masters' Association of Wales, and we have hopes that they will take the matter up earnestly and find some solution of the present difficulties. Others have taken the same steps, and we hope from the combined movement some good may come in the future. We hope that you are also taking the matter up with your Chamber of Commerce, as it will be by agitation all round that we may hope to effect an improvement in the interest of the honest dealer.

As to the sale of spurious quantities of tin plates, it must be borne in mind that it is not so much the difference in price, which may only be 5 or 6 cents; it is in the amount of tin coating that the real difference comes in. A genuine coke tin plate, even if heavier coated than usual, cannot be substituted for a genuine charcoal, inasmuch as on account of being harder it cannot be used for work where a charcoal plate is essential. Bessemer steel, to a certain extent, would answer purposes where Siemens is asked for. The point of the charge seems to be, therefore, not so much in the name as in the fact that the Bessemer plates were often heavier coated than common coke, and then sold as charcoal. The sum total seems to be that tin plates should be stamped and marked according to what they really are.

Pattern for Funnel and Spout.

The accompanying illustration shows how to lay out the patterns for a funnel with spout, the drawing being made to avoid unnecessary lines and to simplify the work as much as possible. Draw the center line A B, extending it indefinitely toward K; next draw the elevation of the funnel, making A D or A C equal to one-half of the top diameter, A L the straight height and L E or

Pattern for Funnel and Spout.

L F one-half of the bottom diameter. Then make L B the straight height of the spout and B I or B H the one-half diameter of the bottom. In practice the one-half elevation A C F H B can be omitted. Now extend the slant lines D E of the funnel and E I of the spout until they intersect the center line of the funnel A K at J and K respectively. Now with L as center and L E as radius describe the quarter plan on the line F E, as shown by E 1, which divide into equal spaces, as shown by the small figures 1 to 4. Then for the pattern for the funnel use J as center, and, with radii equal to J E and J D, describe the arcs E M and D N. Now set the dividers equal to the spaces in the quarter plan, and step off four times this amount on the arc E M, as shown. From J draw a line to M, extending it until it intersects the arc D N at N. Draw radial lines through the arcs at the quarter divisions, as shown. Then will D N M E be the full pattern for the funnel minus edges. If the pattern was desired in quarters or halves cut as desired on the lines shown in pattern.

In precisely the same manner obtain the pattern for the spout using K as center and K I and K E as radii with which strike the arcs O P and R S, as shown. Then lay off on the arc O P four times the amount of spaces in the quarter plan 1 E L, all as shown.

N. & G. Taylor Company's Extensions.

N. & G. Taylor Company of Philadelphia, Pa., are making extensive additions and improvements to their works. They are building another mill at Cumberland, Md., which will give them eight mills. They also have other improvements in contemplation there. At their tin plate works in Philadelphia they are making extensive alterations and building a very large warehouse, fully equipped with electrical elevators for the rapid handling of their product. The box department and the black plate department are also being enlarged and another story added to this building. They are also enlarging their smelting works to meet the great demand for their fine makes of solder, babbitt metals, &c.

The Maryland Sheet Steel Company.

As reported in our last issue, the Maryland Sheet Steel Company have been organized and have purchased from the Crucible Steel Company of America the plant formerly operated by the Cumberland Steel & Tin Plate Company, at Cumberland, Md. The crucible steel portion of the plant will be dismantled. The remainder of the plant will be operated. The equipment consists of a 15-ton open hearth steel furnace, a 16-inch three-high sheet bar mill and four sheet mills, two with rolls 40 inches long, and two with rolls 56 inches long, all being 26 inches in diameter. It is the intention to make open hearth steel, casting small ingots and rolling them into slabs on the bar mill for the sheet mills, which will produce heavy gauge sheets, from 9 to 18 gauge. There is a forging plant of five hammers, which will also be operated. The company have a paid up capital stock of \$100,000, which covers the purchase price of the plant. The directors are A. F. Baumgarten, H. H. Dickey, H. E. Weber, H. E. Henderson and Nathan A. Taylor. Mr. Baumgarten has an office in the Park Building, Pittsburgh, which will probably be the sales office of the company. H. H. Dickey is one of the former owners of the plant, and Nathan A. Taylor is of N. & G. Taylor Company, Philadelphia, whose black plate plant adjoins the company's plant.

FLASHINGS.

CHARLES MCSHERRY of Marlin & Co., Pittsburgh, Pa., is about to embark in the manufacture of Sheet Metal Working Machinery. It is stated that Mr. McSherry will secure a building in Pittsburgh and equip it with the latest improved machinery for the manufacture of the Hercules Shears and a full line of Sheet Metal Working Machinery.

It is reported that the officials of the Newport Rolling Mill at Newport, Ky., have refused several offers for the removal of their plant to other points. The company have been increasing their facilities at Newport and contemplate further extensions of both buildings and machinery. Among the possibilities of the future is the erection of a Steel mill for the production of the raw material with which to manufacture the company's product of Sheets.

THE CINCINNATI PUNCH & SHEAR COMPANY, Cincinnati, Ohio, formerly the Wais & Roos Punch & Shear Company, have received a large order for Sheet Metal Working Machinery from Hawaii. They have recently made shipments of their Machines to South Africa and Australia.

THE NEW PROCESS GALVANIZING COMPANY of Niles, Ohio, recently taken over by the Youngstown Iron, Sheet and Tube Company of Youngstown, will continue to be operated at the old location until the spring, when the plant will be removed to Youngstown.

The business of the International Metal Lath Company of Niles, Ohio, has been growing so rapidly that the company will soon find it necessary to erect additional buildings for the accommodation of their trade. They have recently completed the installation of a new 44-ton expanding machine at their works.

THE WAUKESHA SHEET STEEL COMPANY of Waukesha,

Wls., have placed three new Sheet mills and their galvanizing plant in operation. Three tin mills and a Tin house will be started early in January.

THE CARNAHAN TIN PLATE & SHEET COMPANY, Canton, Ohio, have not fully decided to build a Steel plant in connection with their Plate and Sheet mills, but the prospects are that they will erect a plant with a capacity of from 1000 to 1500 tons per week. The matter will be settled within the next 30 days.

THE NEW SHEET plant being erected at Newcomers-town, Ohio, by the Tuscora Steel Company is rapidly nearing completion. The main building, which is to contain four hot mills and their complement of cold mills, is 110 x 256 feet, the galvanizing department, 50 x 120 feet, and the corrugating and roofing department 62 x 240 feet. The first two buildings are completed and awaiting the installation of the machinery, and work on the third is well advanced. There has been considerable delay in getting the equipment, and the plant will not be ready for operation as early as was expected. The product will be Black and Galvanized Sheets.

WE have received from George Callahan & Co., 218 Front street, New York, a card circular which they are distributing in the interests of their Silicate of Iron Paint. It is explained that Silicate of Iron is composed of sesquioxide and silicate of alumina, and the claim is made that it will stand longer and cover better than any Paint in the market. Samples attached to the card show that the Paints are made in gray, drab, olive, oxide red, yellow, brown and lead colors. The Silicate of Iron Paints are supplied ready for use in $\frac{1}{2}$ and 1 gallon cans, 5-gallon buckets, half barrels and barrels. It is claimed that the Paint is strictly water proof; will hold its color, and will not corrode, nor peel, nor blister. It is recommended for use on roofs and cornices in places where first-class Paint is needed. It is also adapted for all house painting purposes.

THE shortage of coal in South Wales is causing considerable inconvenience to the Tin Plate mills in that district. Several works have been obliged to shut down a part of their equipment in consequence of inability to obtain a sufficient supply of fuel.

E. H. FRIEDRICH, Holyoke, Mass., has the contract for 25,000 square feet of Skylights for the Champion Coated Paper Company of Hamilton, Ohio. F. J. Shea and A. D. Hendricks are now engaged on the construction work.

THE STARK ROLLING MILL COMPANY, Canton, Ohio, have let the contract for a one-story brick warehouse, 50 x 300 feet.

THE PARKERSBURG IRON & STEEL COMPANY of Parkersburg, W. Va., with offices in the Times Building, Pittsburgh, Pa., have placed four Sheet mills in operation, and will start two other mills as soon as completed. The officials of the company are considering the installation of several knobbling fires and puddling furnaces, whereby they will be enabled to manufacture Puddled Iron Sheets and Charcoal Iron Sheets in addition to fine Steel Sheets.

Two additional hot mills have been placed in operation at the plant of the Waynesburg Forge, Sheet & Tin Mill Company, Waynesburg, Pa., and several additional mills are shortly to be built.

THE LAUGHLIN NAIL COMPANY of Wheeling, W. Va., now have their new Sheet mill, consisting of two roughing mills, four Sheet finishing mills and two stands of cold rolls, in full operation. They are also operating a galvanizing plant and corrugating works, together with a Conductor Pipe, Eave Trough and Metal Ceiling factory. The company will not be able to roll all the Sheets used in these departments.

THE negotiations for the erection of a four-mill Sheet plant at Marietta, Ohio, have fallen through, the local Board of Trade being unwilling to provide the \$50,000 cash bonus desired by the promoters.

THE WHITAKER IRON COMPANY, Wheeling, W. Va., are adding three Sheet mills to their plant. The Whitaker Iron Company and the Wheeling Corrugating Company, which are allied interests, now have between them four Sheet mills, with three more being built; four Tin

Plate mills and a tinning and galvanizing department. The Sheet product of the Whitaker Iron Company is all used by the Wheeling Corrugating Company.

It is reported that the corrugating department connected with the Reeves plant of the American Sheet Steel Company, at Canal Dover, Ohio, will be removed and added to the company's plant at Chester, W. Va.

PREPARATIONS are being made at Scottdale, Pa., to add eight new Sheet mills to the Scottdale plant of the American Sheet Steel Company. Work on the additions will be pushed, and it is expected that they will be in shape for operating early in the coming year.

THE MONTROSS METAL SHINGLE COMPANY, Camden, N. J., report a very satisfactory condition of trade in their various lines of goods. Orders have been plentiful, and among them may be mentioned shipments to points in South Carolina, Texas and other Southern States, as well as in the nearby territory, while shipments for export include Mexico, Buenos Ayres and Brazil.

Trade With Canada.

One of the most interesting addresses made by representative business men at the recent National Reciprocity Convention at Washington, D. C., was that of George T. Coppins, general manager of the Walworth Mfg. Company of Boston, Mass., who represented the Boston Chamber of Commerce at the convention. Mr. Coppins took strong ground in favor of more liberal treatment of Canada, as the largest customer for our goods. He spoke, in part, as follows:

There is no logical escape from the conclusion that Canada should be included in any scheme of trades union which is based upon Pan-American necessities. There are only a few great purchasing nations. England, Germany and France lead the list, but so far as our trade is concerned Canada takes the third place, and, in spite of her limited population of 5,000,000, she bought of our products last year \$20,000,000 worth more than France did. Canada, considering the number of its people, is our best customer. The Canadians bought of us last year goods to the value of \$20 per capita. Surely a nation that possesses such an astonishingly good customer cannot afford, on the broad principles of trade, to adopt any policy which threatens to drive him away.

But these large Canadian purchases are not the only considerations to be taken into account. These neighbors to the north of us bought last year more of our products that are classed as manufactured goods than any other nation in the world. Nearly two-thirds of all the merchandise that we sold to them came under that classification. It hardly needs to be explained to this assembly that this is the most profitable species of trade that a nation can possess. It is well to sell wheat; it is better to sell flour. It is well to sell pig iron and steel billets to a foreign people; it is better to sell them tools, hardware, machinery and various other iron and steel commodities ready for immediate use.

A new process for electroplating wooden doors, &c., with copper, brass, nickel or any other desired metal, is announced by a contemporary. The process is described as follows: To preserve the wood and prevent it from warping, it is first treated with linseed oil and resinous gum. It is then varnished, and after conducting metal strips have been fixed around the edges to disperse the current, the whole surface is rendered conducting in one of the several ways known to electrotypers. It is then immersed in the plating solution and the metal deposited upon it by the action of the current. For the decoration and enrichment of carved doors, panels or other architectural parts, as well as for general decorative purposes, such a process should prove very useful.

It is reported that another immense oil well has been struck at Baku, Russia, supplementing the great gusher which has been yielding 1,000,000 poods daily since November 17. The new gusher is almost as great a producer. The price of oil at Baku has fallen sharply in consequence of these strikes.

European Heating Boilers.

BY CHARLES F. HAUSS.

IN THREE PARTS. PART SECOND.

(Continued from *The Metal Worker*, November 23, 1901.)

The Bechem & Post boiler is shown in Figs. 55 and 56 with its automatic regulator, *f*; magazine feeder, *b*; safety pipe, *c*; steam supply pipe, *d*, and the water of condensation return pipe, *e*. This boiler is used for low pressure steam heating. The fire burns toward the front,

pounds, which is secured by the safety pipe being about 16 feet high above the water line. Most of the countries of Europe have copied this law; but Belgium, for instance, uses two safety valves, while France and England are satisfied with one.

Figs. 57 and 58 show the Excelsior boiler for hot water, and Figs. 59 and 60 the Grove boiler for hot water, both of which are designed for quick heating up and holding the heat a long time with their immense fuel space.

Figs. 61 and 62 represent the Rietchel boiler for low pressure hot water heating, in which the gases pass up-

EUROPEAN HEATING BOILERS.

then around the outside. The fire surface is rated to supply on an average 2600 heat units per hour, or 9 square feet of radiation per square foot of fire surface. This is a riveted boiler, built according to the laws of Germany—that is, it must stand 90 pounds of test pressure—and it is operated with the open safety pipe, which must be of the following dimensions:

Fire surface in square feet.	Up to 15	25	45	60	70	85	For all larger boilers.
Diameter of pipe*, in inches.	1 1/4	1 1/2	2	2 1/4	2 1/2	2 3/4	3

* In America, where the odd 1/4 and 3/4 sizes of pipe are not made, the dimensions given may cause surprise, but they are commercial sizes in Germany.

The limit of pressure allowed in use on a low pressure steam boiler is one-half an atmosphere, or 7.35

ward through the circle of tubes around the magazine, then down on the outside.

In Fig. 63 is shown the Martine boiler for low pressure steam heating with a complicated but effective regulator. On all first-class work in Germany the first cost of an apparatus is never considered, and they will pay as much for a reliable regulator as for the boiler.

Figs. 64 and 65 show a type of horizontal tubular hot water boiler, much in use all over Europe, which is provided with a large magazine, either round or oval in form. The products of combustion pass first to the back, then forward through the flues shown on each side of the magazine, then back again over the outside surface of the boiler, whence they pass at the rear bottom end of the brick setting into the chimney flue.

In Figs. 66 and 67 are given this same boiler for steam heating.

Figs. 68 and 69 show a return flue boiler with single large central flue. The fire passes first along the bottom outside surface to the rear, then forward to the space X, from which it enters the smoke flue X X, shown in the cross section. Figs. 70 and 71 represent practically the same boiler with a Tenbrink furnace and a slightly different travel of the products of combustion, which in this case is distinctly shown in the sketch.

For all boilers, whether for steam or hot water heating, of the kinds shown in Figs. 59 to 71. Professor Retchel gives the following generally accepted proportions: A flat grate is invariably used in Europe; hence, to

than 600 degrees F., but the temperature of the gases when in constant use should not vary much from 220 to 300 degrees.

Figs. 72 and 73 show the Colomblie boiler, made in Southern France, with very powerful direct surface in the curved tubes, one end of which is expanded into the inner shell, the other into the middle shell, which acts as a diaphragm and guarantees a positive interior circulation. To facilitate repairs, the upper and lower part of the outside shell are bolted together. One specially good point in this boiler is that the water leg, which forms the base, gets larger at the bottom and prevents the easy filling of this part of the boiler with sediment or scale. The boilers are made with from 20 to 600 square feet of

EUROPEAN HEATING BOILERS.

properly burn 100 pounds of fuel per hour, the following size of grate is required:

Kind of fuel.	Total area of grate.—Square feet.	Free air space in grate. Per cent. of total area.
Bituminous coal.....	6¼ to 7½	33 to 50
Anthracite coal.....	11½ to 13½	33 to 50
Lignite	9 to 11	20 to 30
Wood or peat.....	8½ to 9½	14 to 20
Coke	4 to 5	33 to 50

The rating of different boilers should be based as follows: For surface coming in contact with the fire, 6000 heat units, or 33 square feet of two-column direct cast iron radiation, per square foot per hour; for surface on which the flames radiate directly, 5200 heat units, or 28 square feet of radiation; for the return tubes or flues, 3600 heat units, or 20 square feet of radiation, and for the outside or last use of the shell surface, from 1800 to 2600 heat units, or 10 to 14 square feet of radiation, per square foot of fire surface per hour for hot water boilers.

The gases should leave the boiler when the first fire is built, and when first heating a building, at not more

than 600 degrees F., but the temperature of the gases when in constant use should not vary much from 220 to 300 degrees.

Fig. 74 is a wrought iron drop tube boiler (a sort of freak), made in the north of France. Fig. 75 shows another combination of water tube and shell boiler, which is made in Germany, and should be very effective.

In Figs. 76 to 79 are presented four views of a representative pipe boiler for hot water heating, made up of a series of pipe coils connected at the flow and return end into cast iron headers. The advantage of this style of boiler is that any amount of fire surface or water contents wanted can be obtained, as can also the proportion of grate surface. This type of boiler is rated to supply, on an average, 4500 heat units, or 25 square feet of radiation, per square foot of fire surface per hour.

Figs. 80 and 81 show a boiler made up of straight tubes with wrought iron headers, which is termed an American type of boiler. For steam these boilers are equipped with a large steam dome.

The pioneer cast iron sectional boiler of Germany, known as the Strebel boiler and illustrated in Figs. 82 to 88, is made up of oval sections connected with wrought iron slip nipples at the top and bottom. These boilers are made in four models for hot water; the first with from 24 to 48 square feet of fire surface, the second with 30 to 60 square feet of fire surface, and both in from four to seven sections. The third model has from 30 to 110 square feet of surface, and the fourth from 50 to 170 square feet of surface, both of the latter being made in from 4 to 12 sections. As part of this surface is extended, or dry, surface, in the ribs which form the down draft flue on each side, the makers rate them to supply only 2600 heat units per square foot of surface. In this type of boiler the area of the flues increases as sections and grate surface are added. The grate is cast on the sections, and being very heavy and solid where it is flat,

to 3000 heat units. They contain from $2\frac{1}{4}$ to $2\frac{3}{4}$ pounds of water, and hold 2 pounds of coke per square foot of fire surface.

(To be continued.)

Elementary Ventilation.

One of the speakers at a recent educational meeting in Boston, says the *Herald* of that city, emphasized the nature of ventilation as an indispensable adjunct to the training of children, and in doing so told what might be called a story of ventilation under difficulties. He was traveling in Scotland, and, though it was winter time, had determined to call at as many schools as possible, with a view to his projected article on "Education in the Highlands." One small, stuffy place, which looked more like a store than a school, he found devoid

Fig. 85.

Fig. 93.

Fig. 94.

EUROPEAN HEATING BOILERS.

the section is split in the center to allow for proper expansion and contraction. That part of the grate which slants at each side is cored; consequently the grate is always cooled by the water circulating so near it.

Figs. 82 to 85 show the construction of the water boiler, and Figs. 86 to 88 the two different types of steam boiler, the one shown in Fig. 88 being so high that its use is limited to work where a pit is permissible. The makers' ratings indicate that they expect each square foot of fire surface to carry 14 square feet of water radiation, or 9 square feet of steam radiation, which seems conservative enough. The amount of water contained in the water boilers ranges from 2 to 5 pounds per square foot of surface, and in the steam boilers from 8 to $11\frac{1}{2}$ pounds per square foot of fire surface.

In Figs. 89 to 94 are given the Strehla boiler, Figs. 89 and 90 showing the hot water type, and Figs. 91 to 94 the steam boiler. This boiler has a large central magazine, and is made in from 4 to 11 sections, with 67 to 224 square feet of fire surface, rated to carry 16 square feet of radiation for water and 10 square feet of steam radiation per square foot of fire surface, equal

of even the slightest means of air renewal, yet the teacher assured him that it was one of the best ventilated educational institutions in Scotland. As he seemed incredulous, the lady invited him to remain for an hour until the time for recess. He did so. When the time arrived the lady rang the bell. Whereupon the children left their desks, put on their cloaks and coats, formed into processional order, and marched for exercise into the open space outside the school. Meanwhile the windows of the building had been thrown open, and for 10 or 15 minutes the wind was allowed to do the work of the missing ventilation apparatus. That is was snowing hard at the time did not interfere with the experiment.

H. N. BREWSTER & Co., Northampton, Mass., have the contract for plumbing a business block in that city, and a house for George Beams in Florence. They are also installing a heating system in the greenhouses at Smith College, and have installed a hot air furnace heating system in the residences of Professor Cable and Professor Mills, and in that of Mrs. Waite of Hatfield.

John D. Clarke.

John D. Clarke died at his residence, 368 Macon street, Brooklyn, N. Y., on December 3, from neuralgia of the heart, at the age of 54 years. Mr. Clarke was a contracting steam fitter at 276 Water street, New York, where he established himself in business in 1886. He devoted himself to a high class of work and had heated many of the finest residences in the vicinity of New York, as well as some of the large buildings in the city. He was a member of the National Association of Master Steam and Hot Water Fitters and also prominent in Masonic circles. The funeral services were held at his residence on Thursday night and the interment was made in Evergreen Cemetery on Friday. He is survived by a wife, one son and two daughters.

Death of Martin Fallon.

Martin Fallon, one of the best-known plumbers of Brooklyn, N. Y., died at his home, 230 Cumberland street, that city, on November 28. He was born in New Jersey in 1845 and had resided for the past 45 years in Brooklyn, where he conducted a successful plumbing business. He returned to his home from business on Wednesday complaining of not feeling well, and in the night was stricken with congestion of the lungs, from which he died the next day. Mr. Fallon took an active interest in plumbing affairs, having held various offices in the Master Plumbers' Association of Brooklyn, of which body he was a past president. He also served a term as a member of the Executive Committee of the National Association of Master Plumbers. He was a member of St. Albans Lodge, F. and A. M. The funeral services were held at his late home on Sunday afternoon, the Rev. Doctor Stockdale of the Fleet street Methodist Episcopal Church officiating. He is survived by a widow, two sons and two daughters.

Life of Cast Iron Pipes.

In answer to a correspondent asking as to the probable life of cast iron pipe buried in ordinary soil, *Municipal Engineering* gives the following interesting information on the subject:

The only data from observation at hand are found in reports from St. John, N. B., and Los Angeles, Cal. Gilbert Murdoch, superintendent of the water works at the former place, reported in 1892 several observations. In one case a 4-inch main, in use about 33 years in marsh mud, had failed by softening of the outside, and the break took place at some air cells in the body of the pipe.

A 6-inch pipe 52 years old in soft, slaty rock, failed from softening. A 24-inch pipe laid in well drained, gravelly brick clay, 36 years old, failed from inherent defects in the pipe, the outside of the pipe being sound and the inside having a coat less than 1-16 inch thick. None of these pipes were protected by coatings. The conclusion regarding the 24-inch pipe in well drained gravelly clay was that, aside from the defects in manufacture, its life would have been practically indefinitely long.

J. H. Dockweiler, City Engineer of Los Angeles, Cal., reported the condition of the water works in 1897. The pipe was uncovered in 318 places. Cast iron pipe 28 years old was found in a perfect state of preservation. In sand or loam the bare pipe metal did not rust. In hard adobe soil there was some rust, but the pipe was practically uninjured. In all cases the original asphalt coating had practically disappeared. A later report of a board of engineers, consisting of J. D. Schuyler, A. L. Adams, A. H. Koebig and J. B. Lippincott, estimated the depreciation of the water pipe in the city in the better soils at 1.25 per cent. per annum, indicating a life of 80 years, and in the poorer soils at 2 per cent. per annum, indicating a life of 50 years. The effect of the soil upon the outside of the pipe and of tuberculation upon the inside are both allowed for in these estimates.

In case there is opportunity for electrolysis from street railway or other electric leakage, the life of pipe

is very greatly shortened. Some chemical conditions of soil which will shorten the life of pipe will doubtless be met with.

An Electric Water Heater.

In the accompanying illustration is shown an electric water heater patented by Waldo F. Follett of New Haven, Conn., who states that the chief object of his invention is to provide an electric water heater of cheap and simple construction, and sufficiently efficient to take the place of the usual coal burning water heater used in connection with a hot water piping system. From

An Electric Water Heater.

the illustration it may be seen that the electric water heater consists of a cast iron box, in which there are waterways, and also space for the resistance coils for heating the water. Provision is made for connecting the necessary wires, and a switch is provided for the control of the electric current. The resistance coils are so arranged as to be protected from injury and to prevent short circuiting. The simplicity of the construction enables any necessary repairs to be conveniently made. This heater, it is pointed out, may be used for heating water for any purpose where an electric current is obtainable, but it was especially designed for use in connection with radiators. The heater may be located in a basement in connection with stacks of indirect radiators, or may be connected and used in the same manner as a coal burning hot water boiler. It has the advantage that the electrical regulating switch may be located at any convenient point in the building and the temperature of the building regulated without ever going to the cellar. The heater is shown in connection with a portable radiator. It is available for use wherever there are electric light brackets, and is especially adapted for use in offices, hotels and hospitals, where heat may be required quickly or temporarily. The apparatus may also be connected with the kitchen range boiler to prevent it from freezing when the house is closed, or for furnishing hot water in the summer season, when the coal fire is supplanted by a gas or oil range.

Competition in the Australian Plumbing Trade.

It is certainly true, says the *Australian Ironmonger*, that competition in the plumbing business is keener now than ever before. Especially is this the case in Melbourne, a city which should tell another tale, considering the installation of its new and comprehensive system of sewerage. Few, if any, plumbing businesses in Melbourne are returning a fair percentage of profit. The competition met with on the part of "carpet bag" plumbers is a serious element to the man who has business premises to maintain. For this state of things some remedy must be sought.

It is difficult to suggest a proper form of relief. Preferential buying has been proposed, and if practicable would be to a large extent a remedy against excessive competition. It is, however, a hard matter to bring such a system into operation.

It should be impossible for a man who has not qualified himself to conduct a plumbing business to obtain material on the same terms as one that has. Melbourne, through its faulty licensing system, is teeming with laborers, drainers, bricklayers, bootmakers, &c., who are buying their material on the same terms as the recognized master plumbers, and so are able to compete against them, to their disadvantage.

Another remedy which may be applied is in respect to the free and easy credit system in vogue. This should in some way be curtailed by agreement between the merchants and plumbers. Any half learned journeyman who cannot find employment at standard wages because he cannot earn the money for the employer, can start business without capital. Merchants are too willing to let him have material, and too many open accounts are kept. He immediately sets out to hunt up all kinds of jobs, and is willing to take them up without any margin of profit, in order to establish himself. If things do not come right he does not pay the merchants, and after a compromise starts afresh.

Had plumbers' accounts to be settled when due, more care would be exercised in estimating, and the margin of profit would be considered. Merchants in combination should insist on all accounts being paid within two months, on pain of defaulters being placed on a cash on delivery basis. This might cause a few hardships to good men, but it would shut down a lot of competition and make speculators careful in tendering. A plumber getting behind in his payments, and being required to pay cash for any further goods, would often be saved from bankruptcy. The success of a business depends on the margin of profit, and not on the amount of work done.

Holding the Water Line.

A correspondent of *Marine Engineering* tells of an experience he had with an obstinate blow off pipe in the following words: "A number of years ago, while employed as assistant engineer on an old fruit ship running to New York, the following mishap occurred. The machinery of the ship consisted of an old single engine 42 inches square, with all pumps attached, and a boiler of the fire box return tubular type. As we had neither evaporator nor tanks, and our steam pressure was low, we used salt water. We had heavy weather all the trip, and were about off Hatteras, bound to New York. I had just gone on watch, and finding the density of the water in the boiler too great, started to blow off a little. On attempting to close the blow cock it stuck fast and could not be shut; and as there was no valve on the ship's side we were in a bad fix—a gale of wind blowing, the sea running high, the blow cock wide open, and the water blowing out faster than it could be fed in. To stop the engine meant to fall off in the trough of the sea and be swamped, and it was only a question of time when she would stop herself if that blow off was not closed. Realizing the necessity of prompt action, I looked around and my eyes fell on the coal hammer and a heavy sledge. Calling the fireman to hold his hammer to one side of the blow off pipe, which was copper, I took the sledge and began to flatten the pipe. Fortunately, the brazing held, and we succeeded in hammering the

pipe out flat, thereby stopping the water. An old rivet was afterward found wedged in the blow cock and preventing it from closing."

We do not pretend to know much about the perils of falling into the trough of the sea, says the *Locomotive*, although we have always heard it said that it is not a proper thing to do, if one can help it. But we do know something about the perils of hammering a blow off pipe when the boiler to which it is attached is under pressure; and unless the trough was a pretty bad one, we think we had rather take chances with it than with the hammer.

Becker's Rubber Bucket for Chain Pumps.

The accompanying cuts represent rubber buckets for chain pumps, offered by C. L. Becker, Keokuk, Iowa. As shown in Fig. 2 the metal portion of the bucket consists of two parts, which can be opened or closed. These

Fig. 1.—Becker's Rubber Bucket for Chain Pumps.

buckets, it is explained, can be hooked into or removed from the chain link at pleasure, without the use of tools and without injury to the chain. The advantage claimed for this bucket is that the chain links do not have to be

Fig. 2.—Metal Parts of Becker's Rubber Bucket.

opened in order to insert the bucket, and that there is, therefore, no danger of weakening or breaking the links of the chain.

New York City Notes.

Borough President Cantor of Manhattan has selected former Assemblyman Perez M. Stewart for Superintendent of Buildings in that borough. Mr. Stewart is a practical builder and has erected many apartment and private houses, principally in the Riverside section of the west side. The plumbing trade can look for the fairest treatment from Mr. Stewart.

* * *

Chief Inspectors of Plumbing P. J. Andrews and Gen. Geo. D. Scott of Manhattan and the Bronx, respectively, together with John Renahan, president of the Examining Board of Plumbers, are strongly indorsed by the trade for retention in their present positions as most efficient officers.

* * *

For a man whose picture formed part of an obituary notice in an out of town trade paper, William J. McDermott of 381 Bleecker street, Manhattan, was congratulated at the last meeting of the Manhattan Branch for being a lively corpse. The error arose from a similarity of names with M. J. McDermott of Tremont, whose death was noticed in a previous issue.

* * *

The United Central Council of Building Trades, formed from the old Board of Delegates and Building

Trades Councils, has been organized for the purpose of doing away with sympathetic strikes. At its meeting held last Monday, both organizations of journeymen plumbers were excluded from membership, together with the Architectural Iron Workers' Union, until differences in their trades can be settled and their strikes called off.

* * *

Owing to the strike and other troubles on the Ansonia Hotel, water was allowed to remain in the supply lines during the recent cold snap, and Milton Schnaier reports that over 60 miles of pipe is frozen solid.

* * *

There is a rush of plumbers to file their bonds with the Sewer Department and to register with the Board of Health, both of which things must be done during the month of December.

* * *

The new heads of city departments will find many good men in places from which they can hardly be spared, such as Robert McNichol, permit clerk in the Sewer Department; Geo. G. Stillwell, in the Department of Highways; Thomas Stanton and Jos. Lewis, in the Water Department, and Patrick Wolf, in charge of meters in Manhattan; Sherwood Kipp in the Highways Department in the Bronx, and many others in other departments and boroughs.

Death of Henry J. Dayton.

Henry J. Dayton, who for 44 years had been prominent in the Furnace and Heating trade of Brooklyn, N. Y., died at his home, 440A Sixth street, on Wednesday, December 4. Mr. Dayton was born at Westfield, Mass., in 1832, and after an education in the schools of his native town, entered business. In 1857 he went to Brooklyn and associated himself with John Q. Adams & Son. The firm afterward became Dayton & Carter, and after the death of Alanson Carter Mr. Dayton succeeded to the head of the firm, which became Dayton & Montgomery, this concern having been in existence since 1886. He was active in his connection with the First Reformed Church of Brooklyn. He leaves a wife, who was a Miss Roxanna Howes of Ashfield, Mass., and a descendant of Puritan ancestry. He had been married for 40 years. His son, Ralph E., and a daughter also survive him. The funeral services were held at his late home on Friday evening at 8 o'clock, the Rev. Dr. Albert J. Lyman officiating.

The P. and S. S. League.

On Monday the Central Foundry Company team won two games in the bowling tournament of the Plumbing and Steam Supply League in New York, and the John A. Murray team lost two games, while the H. P. Read Lead Works bowlers had the bitterness of their defeat sweetened by a victory. The last two contests were close. On Thursday night the team of E. F. Keating was short one man, and, in consequence, suffered two defeats, while the team of Ronalds & Johnson Company, New York, won both their games and the team of F. Adey & Co. scored a victory and a defeat. The scores for the week were all below 700, with the exception of the 716 of the Central Foundry Company on Monday night.

At the regular meeting of the Master Plumbers' Association of Buffalo, N. Y., held November 25, a number of the members were balloted upon for the indorsement of the association for the position of member of the Board of Examiners of Plumbers and Plumbing. A vacancy on the board occurs December 31, 1901, by the expiration of the term of Charles B. Huck. A number of ballots were necessary to finally determine the successful member, Charles B. Huck, he receiving the unanimous indorsement of the association. Mr. Huck is also president of the New York State Association of Master Plumbers and a former president of the local association.

Heating and Plumbing Notes.

THE disposition of the manufacturers of Boilers to be in a position to secure radiation through sources over which they have an influence has resulted in a report that the new year will finish with a new Radiator plant in full operation, which, it is rumored, will produce a larger amount of radiation during its first year than has ever been put out by any new Radiator plant. This is but one of the different reports in reference to Boilers and Radiator productions which are current in the heating trade at this time.

JOHN BEST, a pioneer manufacturer of Lancaster, Pa., and head of the Best Boiler & Engine Works, the Lancaster Radiator & Tube Company and other local concerns, died from heart disease on November 25 at his home in that city, in the eightieth year of his age. In 1890 Mr. Best purchased the Lancaster Radiator Company, which he added to his works.

THE WEIR STOVE COMPANY, Taunton, Mass., are sending out a very attractive piece of trade literature, entitled "Stories of the Glenwood by People Who Use Them," devoted to their Glenwood Hot Water Heaters. Under the name Glenwood, the company manufacture Hot Water, Steam, Warm Air and Combination Warm Air and Hot Water Heaters. The first few pages of the catalogue show general and broken views of the Glenwood Water Heaters, so that the construction of the ash pit, grate and fire and water sections, and the fire and water travel, and the regulating dampers can be readily understood. These are followed by some 40 pages, each of which presents a half-tone engraving of a New England residence in which the Glenwoods are used. The lower portion of each page is devoted to testimonial letters. Side heads printed in red ink call attention to the principal feature of the testimonial. These "Stories of the Glenwood," if used by an enterprising steam fitter among prospective purchasers in his locality, should have the effect of substantially increasing his trade.

At a meeting of the stockholders of the United States Radiator Company, held at Dunkirk, N. Y., last week, S. L. Clement of Buffalo was elected a director to fill a vacancy. The directors elected the following Executive Board: R. J. Gross, F. W. Smith, W. C. Marsh, Newell F. Gould and Harry S. Martin.

SUPERINTENDENT HARRY H. BENDER of the New York State Department of Public Buildings has completed the renovation of the plumbing system in the Executive Mansion, which was vacated by Governor Odell last spring on account of the sickness of his daughter. Under Mr. Bender's charge, not only the plumbing system, but the heating system also has been put in perfect working order. After the plumbing work was completed it was subjected to a final smoke test, and found to be proof against the escape of air from the sewer and house drainage system.

"It is authoritatively learned," says the *Express* of San Antonio, Texas, "that the result of the suit brought by Attorney-General Bell against the Master Plumbers' Association of Texas, will be that the officers of the association will be fined an amount approximating \$3000, which will be paid and the matter ended."

SAMUEL GIBSON died at his residence, 2304 Wylie avenue, Pittsburgh, Pa., after a protracted illness, aged 54 years. For a number of years he conducted a plumbing business on Center avenue. He is survived by a widow, one son and one daughter.

HAWLEY & Co., St. Paul, Minn., have the contract for the plumbing and gas fitting in the new Norwegian Hospital in that city.

THE CHARLES THATCHER COMPANY, Waterbury, Conn., bid \$2280 and secured the contract for a plumbing system for the Bank Street School, in that city.

F. P. STEWART & Co., Ithaca, N. Y., have the contract for plumbing and steam heating the Cayuga House and the Boyer Block, in that city. They are also heating the Van Kirk and Foote houses.

H. L. SAWYER, South Framingham, Mass., has the contract for putting in the heating and ventilating ap-

paratus at "The Gorman," South Framingham's new playhouse and hall.

A FIRE visited the plumbing and hardware establishment of Erastus S. Chesebro, Stonington, Conn., last week, the principal loss resulting from the water used in quenching the fire.

P. H. GARRITY of Waterbury, Conn., is heating and plumbing the new residence of D. M. Rogers. He has just installed a hot water boiler in the residence of John Byrne, and has the contract for plumbing the residences of Charles Roper and James Finn, in Waterbury.

THE rolling mill of the Tube plant of the Alabama Tube & Iron Company, at Helena, near Birmingham, Ala., has begun operations, and by the middle of the month it is expected that the whole plant will be in running order. From 200 to 250 men will be employed.

THE Commissioners of Washington, D. C., will receive bids until December 14 for a steam power plant and connections at the Trumble Street Pumping Station.

THE authorities of New Haven, Conn., are considering an ordinance providing for the licensing of journeymen plumbers.

H. C. PETERSEN & Co. of Utica, N. Y., bid \$2000 and secured the contract for heating and plumbing the new County Clerk's Office for Madison County. They will use a Low Pressure Steam Heater made by the International Heater Company.

THE heating of the new shops of the Reading Company, at Reading, Pa., is now engaging the attention of the officials. The plant will be located in the power house and is known as the Foster system. It will require about 23 miles of Pipe, the sizes varying from 1½ to 14 inches. This work, it is thought, will be started soon, and it will take months to complete. The heating will be done by steam, but under a very low pressure. All of the main pipes will run through the conduits which were laid at the time the shop was erected.

THE ALLEN FIRE DEPARTMENT SUPPLY COMPANY of Providence, R. I., who have a branch office in Worcester, Mass., have recently been successful in securing the contracts for heating new buildings erected in the latter city, including the Home and Sever Street School, the Beacon Street Engine House and the Northville School. Their bids on these jobs were \$2347, \$624 and \$1985, respectively, the next lowest bids for the same work being \$3387, \$915 and \$2845.

FIRE of unknown origin destroyed two floors of the four-story brick building owned by Maule & Pancoast, at the northeast corner of Fourth and Locust streets, Philadelphia, Pa., last Tuesday night, damaging the building and its contents to the extent of \$25,000. Maule & Pancoast, manufacturers of Engineering and Steam Fitters' Supplies, occupied the first floor and basement of the building.

THE UNITED STATES RADIATOR COMPANY of Dunkirk, N. Y., under date of December 2, are issuing the following announcement to the trade: "We are pleased to announce the opening of our Minneapolis branch office, 432 and 434 Guaranty Loan Building, where our friends and patrons will receive a cordial welcome and attention at the hands of H. J. Warneke, who will represent the company as manager. We shall carry a complete stock of Radiation to enable our customers to enjoy prompt delivery. We bespeak for Mr. Warneke your continued favor and assure you that it will be our aim to merit your patronage."

THE UNION LEAD & OIL COMPANY, says the *St. Louis Republic*, have decided to make St. Louis, Mo., their headquarters and erect there, in addition to the largest White Lead plant in the world, a plant for turning raw material into Shot, Lead Pipe, Sheet Lead and Plumbers' Supplies. This plant when completed will have a daily output of 15,000 tons. The company and those allied with their interests control the Missouri Lead field.

FROM the time the plant of the Youngstown Iron Sheet & Tube Company, at Youngstown, Ohio, was originally projected, it was their intention to build an Open Hearth Steel plant to supply their own Steel and make

them independent of the open market. Recently the directors of the company increased the capital stock \$1,000,000, and this money will be used for the building of a basic Open Hearth Steel plant, to furnish steel for the new Tube and Sheet mills, which they are building. Detailed plans of the new plant are being prepared and work will be started in a short time. It is likely the new steel plant will be ready by the latter part of 1902. The new sheet mill of the Youngstown Iron Sheet & Tube Company is rapidly nearing completion, and will be ready for operation within 60 to 90 days.

FLINT & WALLING MFG. COMPANY, Kendallville, Ind., have just issued general catalogue No. 42, which illustrates and describes their line of Star Wind Mills, Hoosier and Fast Mail Pumps and Auxiliary Goods. The catalogue contains nearly 250 pages, is attractively printed and bound, and presents satisfactorily the extensive line to which it is devoted. In the early pages the growth of the company's business is impressively indicated.

LAIB COMPANY, dealers in Mill, Factory, Steam and Plumbers' Supplies, Louisville, Ky., are about to move to more spacious quarters, where they will be in a better position to serve their customers than heretofore. After January 1 they will be located in their new store, 439 West Main street, which extends through an L to 153 Fifth street, the latter premises being used for shipping purposes. The company have just issued a 450-page catalogue, illustrating their full line of goods.

New Firms and Changes.

THE UNION MACHINE SHOP & PLUMBING COMPANY of Union, N. Y., have opened a shop on Hanna street, one block from the Erie Depot.

THE GORDON PLENUM LIGHT COMPANY, 205 Market street, Camden, N. J., have been incorporated by J. Fred. Zimmerman, Thomas Gordon and Granville N. Buzby, with a capital stock of \$60,000, to manufacture Gas Governors, &c.

THE TUBULAR INCANDESCENT GAS BURNER COMPANY of Pierre, S. D., have been incorporated with a capital stock of \$500,000 by S. M. Williams, Joseph Agust and L. L. Stephen.

THE HENRY ELECTRICAL COMPANY have been incorporated at Denver, Col., with a capital stock of \$1,000,000, for the purpose of manufacturing and putting on the market a new electrical device, the invention of the late J. C. Henry of Canon City, for heating and lighting electric cars. C. F. Elliot is president, M. F. Hardy vice-president, and James H. Peabody, president of the First National Bank of Canon City, is the chairman of the Board of Directors of the new company. It is said that with this device electricity is generated through the agency of the axles of cars, when running at a speed of 4 miles an hour. The surplus generated while the cars are running is gathered in storage batteries for use when the train may be standing still or side tracked. It is claimed that cars may be lighted, warmed or cooled, as the season may require, through the use of this apparatus.

THE R. C. INSLEE COMPANY have succeeded the Harlow-Inslee Company as sole New England agents for the Flushometer, the Kenney system. H. N. Libbey has been appointed manager of the new company, with offices at 176 Federal street, Boston, Mass.

THE AMERICAN WARMING & VENTILATING COMPANY of Elmira, N. Y., have been incorporated with a capital of \$10,000. The directors are R. M. Geddes of Newark, N. J.; L. D. Shoemaker and George McCann of Elmira.

THE FREEMAN-BRYANT MFG. COMPANY of 419 Market street, Camden, N. Y., have been incorporated with a capital of \$1,000,000 to manufacture Boilers, Pumps, &c. John W. Freeman, Walter G. Bryant and C. H. Cole are the incorporators.

THE PHOENIX STEAM HEATING COMPANY of Chicago have been incorporated with a capital stock of \$25,000 by George Clements, Augustus I. Sanborn and James D. Robertson.

CHARLES A. KUNZ, formerly of the firm of T. Kunz & Sons, at Findlay, Ohio, has opened a plumbing and tin shop at 678 South Main street, Findlay, Ohio.

Some Characteristic Signs

The first function of the sign which a man hangs in front of his place of business is to advertise that business, and the question that the steam fitter, gas fitter, plumber, tinsmith and cornice maker should ask himself is, "Why do I patronize a carpenter when all the necessary materials for the painter to work on are to be found in my own shop?" If the sign is to advertise your business, it should by all means, if possible, be characteristic of the business. It should be made of materials used in every day work, and so constructed as to show the

Characteristic Signs.—*Fig. 1.*—*A Sign for Steam Fitters and Gas Fitters.*

superiority of the handicraft of the workmen in your employ.

For example, the steam fitter and the gas fitter work almost entirely in iron pipe. In Fig. 1 a sign is shown that was used by some students at the New York Trade School in connection with the iron piping for the hot and cold water service of an upright double boiler, which was their exhibition piece of work for the season. The frame of this sign is made of iron pipe and fittings, the pipe being bent to lend some attractiveness to its appearance. The frame supports a piece of galvanized iron used as a ground for the lettering. It will not require any considerable ingenuity for a good mechanic to vary the style and shape in order to make a swinging sign to hang over a sidewalk, or a sign to be supported

Fig. 2.—A Sign for a Plumber.

by an upright post, or a sign to fasten to the wall, similar to the one shown.

If the plumber needs a sign, the example presented in Fig. 2 should especially meet with the approval of plumbers of Scotch and English descent, suggesting, as it does, the time when the shield, spear and battle axe were the principal implements of warfare. Such a sign affords an opportunity for the plumber to show his skill in bending the pipes into graceful and ornamental shapes, as well as his dexterity as a lead beater in beat-

ing up the spear head and the axe head. The wiped joints will demonstrate his handiwork, and the contrast between the lead pipe, the white solder and the soil used will give additional life to the design. Sheet lead may be used for the ground on which the lettering is to be done. If the whole sign, when completed, is covered with a water proof varnish, it will retain its appearance

Fig. 3.—Another Design Suitable for a Plumber.

until it can be replaced by another characteristic sign of different design to attract further attention.

A design that might be followed for the second attempt is that shown in Fig. 3, which is also the work of students at the New York Trade School. In this example the scroll so frequently used in ornamental work is a conspicuous feature. The background, which in this instance was used for the index in connection with an elaborate system of piping, affords ample opportunity for the plumber to present his name and the character of his special business.

The business man who runs a tin shop in connection with his furnace, roofing and general sheet metal work-

Fig. 4.—A Sign that Many Can Use.

ing business will find in Fig. 4 a sign used by a concern doing business on Columbus avenue, New York. The ground consists of a piece of sheet iron, around which is an ornamental scroll frame, made of band iron $\frac{1}{8}$ inch thick and 1 inch wide, which readily lends itself to the bends necessary to form the ornamental shapes presented. The sheet iron is attached to the scroll frame by means of bolts which are split at one end and provided with rivet holes for fastening to the sheet iron. The supporting bar may either be forged in the tin shop or by a smith of deeper dye—the blacksmith, who is better qualified for working in heavier iron. One end may either be imbedded in a brick wall or provided with offsets with holes for fastening to the frame—

work of a building by means of wood screws, the outer end to be supported by means of wire guys.

A scroll of sheet metal, shown in Fig. 5, is suggestive of the ornamental architectural sheet metal work produced in a modern cornice shop, and is as well adapted for the tinsmith and the stove dealer as for the cornice and skylight maker.

Signs of this character, if adopted by the trade, would be somewhat novel, and if widely used might enable the general public to locate a steam fitter's, plumber's or tinsmith's shop as readily as the barber shops are located by the striped poles universally used by

Fig. 5.—For the Architectural Sheet Metal Worker.

tensorial artists. Such signs, moreover, possess the additional merit that they can be produced in the shops of those who use them, whereas the barber will still be under the necessity of calling upon the carpenter as well as the painter.

AMERICAN IRON AND STEEL STATISTICS.

The annual report of the American Iron and Steel Association for 1900 has just been issued by James M. Swank, general manager, 261 South Fourth street, Philadelphia. The publication of this report has been delayed much beyond the usual time because the association has had in hand simultaneously the preparation of the *Directory of the Iron and Steel Works*, to be issued in a few weeks. The presentation of statistical information relating to the American iron trade has not been seriously delayed, however, as the statistics of various in-branches of trade have been published from time to time in the *Bulletin* as fast as collected from the manufacturers. The report gives the information in much greater detail than the preliminary figures thus published. Forming a part of the report is a paper prepared for the United States Geological Survey, which is devoted to a review of the progress made by the world's iron and steel industries down to the close of the nineteenth century. A valuable feature of this paper is a chronological record of the development of the iron and steel industries of the United States from 1619 to 1900, giving the principal events in that development and a summary of the grand results. Following are some of the figures of domestic production given in the report:

PIG IRON.

Twenty-one States made pig iron in 1900, the same number as in 1899. The total production of pig iron in 1900 was 13,789,242 gross tons, against 13,620,703 tons in 1899, 11,773,934 tons in 1898 and 9,652,680 tons in 1897. The production in 1900 was 168,539 tons larger than in 1899.

The production of pig iron in the second half of 1899 and the first half of 1900 aggregated 14,974,105 tons, or

almost 15,000,000 tons. The production in the second half of 1899 was 1,042,369 tons larger than in the first half, but the production in the second half of 1900 was 1,495,896 tons less than in the first half. The large production in the second half of 1899 and the first half of 1900 was due to the extraordinary demand accompanying and following the boom of 1899, and the decline in production in the second half of 1900 was due to the subsidence of the boom.

In the first half of 1901, however, there was again an increase in the production of pig iron, the output in that period amounting to 7,674,613 tons, or many thousand tons more than in either the second half of 1899 or the first half of 1900. The present year promises to yield a total production in round numbers of 15,500,000 tons. We estimate the value at the furnace of the pig iron product of 1900 as amounting to \$259,944,000.

BESSEMER STEEL.

The total production of Bessemer steel in the United States in 1900 was 6,684,770 gross tons, against 7,586,354 tons in 1899, showing a decrease in 1900 of 901,584 tons, or almost 12 per cent. The production of 1899 was the largest in our history.

OPEN HEARTH STEEL.

The total production of open hearth steel in the United States in 1900 was 3,398,135 gross tons, against 2,947,316 tons in 1899, an increase of 450,819 tons, or over 15 per cent. Our production of open hearth steel has more than doubled in the last four years.

In 1899 the production of open hearth steel by the basic process amounted to 2,080,426 tons and by the acid process to 866,890 tons. In 1900 2,545,091 tons were made by the basic process and 853,044 tons were made by the acid process.

TIN PLATES.

The duty on tin plates and terne plates provided for in the tariff act of 1890 went into effect on July 1, 1891. From that date until the close of the fiscal year ending on June 30, 1897, the statistics of our production of tin plates and terne plates were regularly collected for the Treasury Department by Col. Ira Ayer, special agent. For the second half of 1897 and the year 1898 they were collected by *The Metal Worker* of New York, and for 1899 and 1900 they have been collected by the American Iron and Steel Association. From the data thus obtained we have compiled the following table in gross tons of our production of tin plates and terne plates in the calendar years 1891 to 1900, the figures for 1901 being for the last six months only. The production of dipping plants is included in the figures given:

Calendar years.	Gross tons.	Calendar years.	Gross tons.
1891 (last six months).	999	1896.....	160,362
1892.....	18,803	1897.....	256,598
1893.....	55,182	1898.....	326,915
1894.....	74,260	1899.....	360,875
1895.....	113,666	1900.....	302,665

PLATES AND SHEETS.

The production of plate and sheet iron and steel in the United States in 1900, excluding nail plate, amounted to 1,794,528 gross tons, against 1,903,505 tons in 1899.

The authorities of the United States Patent Office have handed down an opinion in the case of Charles E. Tripler of New York against Professor Carl Linde of Munich, Germany, relating to the latter's priority of invention for the intensifying process of making liquid air. Professor Linde announced in 1895 that he had discovered a practical method of making liquid air in large quantities, and at a comparatively small cost. After applying for a patent in this country and in several foreign countries, he published in scientific periodicals full details of his process. Mr. Tripler filed application for a patent on a similar invention in 1897, asserting that he had discovered it in 1891. He formed a company to exploit his process and disposed of large amounts of stock in the same.

The Manufacturers' Club of Philadelphia is reported to have in preparation a memorial to Congress indorsing the metric system.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

CONSTRUCTING A FRESH AIR DUCT.

From H. K., Weatherly, Pa.—I have a fresh air duct to make out of No. 22 galvanized iron, as shown by the sketch which is herewith inclosed. Please advise me through the columns of *The Metal Worker* how to construct and lay it out.

Answer.—In Fig. 1 is presented a reduced reproduction of our correspondent's sketch, which shows a plan view

Constructing a Fresh Air Duct.—Fig. 1.—Plan of the Duct to Be Made.

of a fresh air duct, A, 30 x 80 inches in size at its largest section and 31 feet long, having five branches or outlets of the size as indicated. As our correspondent has sent us no side or end view, we have assumed that a section taken through B C would appear as shown by D, which makes the depth of the duct 30 inches and the side view of the branch 20 inches, as shown in plan. Then, in this case, the connections between the branches and duct should take place on the lines X, X, X, &c., the side of the branch appearing as shown by J E F H in section D, connecting the 20-inch opening of the branch to the 30-inch opening of the duct by means of the curved corners, as shown.

In constructing a large duct of this kind, where a number of sheets are to be joined together, a rigid construction must be provided for. While there are various methods employed, the one shown in Figs. 2 and 3 is usually adopted, as it prevents sagging in the middle. Assuming that iron 36 inches wide will be used, the duct will require a little more than ten widths, as shown by a b c d e f h i j in Fig. 1. All the corners on the entire

Fig. 2.—Method of Locking Seams.

Fig. 3.—Method of Laying Out Sheets.

duct should be double seamed, as shown by A and B in Fig. 2. In A is shown the single edge turned up on top and bottom, while on the 30-inch depth of the duct is added the double edge, as shown, which is closed, using the "dolly and mallet," as at B. At C is shown the standing seam taken through r s in Fig. 1 and riveted at intervals, as at a in diagram C in Fig. 2. This standing lock should be made about 1 inch high, notching out at the ends where the doubled lock B takes place, as shown at b, and turning over a lap on the ends, as at c.

When laying out a large duct of this kind the floor is swept clean, a rough diagram made with chalk upon the same and the sheets dotted, as shown in Fig. 3, in which A is a sheet having a single and double edge and B a sheet having a single edge. The sheets are now laid over one another, so that the line c on the sheet B meets

the second line b on the sheet A, as shown. Of course the sheets should be made even at the ends, B being shown lower to indicate the method of lapping. When all the sheets are laid out to the required length of 31 feet tack the sheets to the floor with roofing nails and draw out the full sized duct, allowing for and notching the laps for double seaming. The sheets must then be marked and bent up on the brake, being careful to have all the numbers toward one side. The duct is then put together at the building, using band iron hangers to fasten against the ceiling or wall. It should be understood that the 30-inch depth of the duct is a plain strip with the necessary edges allowed, while the top and bottom have the standing seams.

FROST ON WINDOWS.

From R. C., Toronto.—I used to have a good deal of trouble with frost on my show windows, and last winter I bored some 5/8-inch holes under the window just below the floor, then a few holes through the floor as close to the window as possible, and another row of them near the ceiling, above the glass. My window is separated from the store by a glass partition. I find that since boring the holes I am never troubled with frost, for the

Circulation of Cold Air Preventing Frost from Forming on Glass.

cold air enters through the holes at the bottom of the window, driving the warm air out of the upper holes and making the temperature nearly as low as that outside, thus preventing the condensation of moisture on the glass.

SUPERPHOSPHATE OF LIME.

From C. R., Pottstown, Pa.—Can *The Metal Worker* or some of its readers tell me what superphosphate of lime is and where I can buy it; also what substance I can use that contains the necessary amount of phosphate? I want to use it in the manufacture of phosphor metals, such as phosphor bronze.

Answer.—Superphosphate of lime is lime that contains an excessive proportion of phosphorus. It is principally derived from bones, which are calcined to drive off fatty matter and carbonic acid gas, which leaves the bones as a combination of lime and phosphorus. The calcined bones are then ground and treated with a solution of sulphuric acid and water, which converts part of the lime into a sulphate which is insoluble in water. The solution is then filtered to remove the sulphate; the liquor is concentrated and dried as a superphosphate of lime. This is melted with fine shavings of copper or tin in a crucible covered with charcoal powder, by which a phosphite of copper or tin is produced, which is used for making the alloy of phosphor bronze. The superphosphate can be obtained through the chemical trade.

CHIMNEY VENTILATORS FOR BACK DRAFT?

From I. E. D., Atlantic, Iowa.—In reply to the inquiry of "C. E. M." in *The Metal Worker* of November 23, I would say that I have had considerable trouble with back draft in chimneys, and where I could not get such a ventilator as mentioned in *The Metal Worker* I have made a cone top, as shown in the sketch. Make the cone large enough to come down even with the top of the pipe and leave a space of about $2\frac{1}{2}$ inches between the

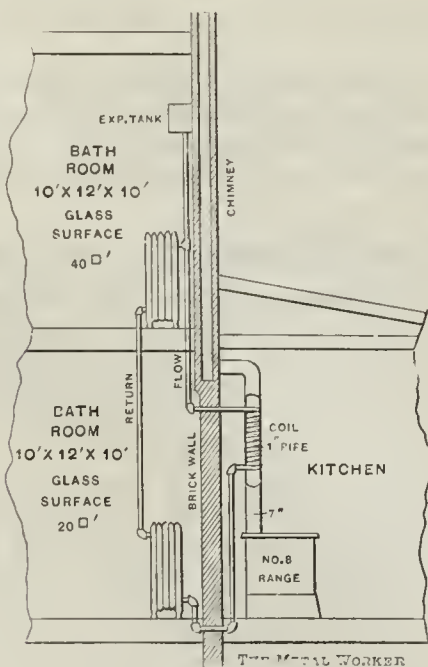

THE METAL WORKER

Chimney Ventilators for Back Draft?

cone and the top of the pipe to which it is attached. If "C. E. M." uses such a cap he will have no trouble with the back draft in his chimney, or, at least, I never have when I have used such a top. If he will turn to page 69 of *The Metal Worker* of November 23 he will see there two styles of the Dayton swinging chimney top, and if he uses either of them he will positively have no trouble. I am now using one of practically the same construction on the side of the roof of a church, where the ridge of the roof is 12 feet higher than the top of the chimney. With this chimney top the chimney works as well as if it rose clear above the roof.

UTILIZING WASTE HEAT.

From Southern Plumber, Georgia.—I would be glad to learn from the readers of *The Metal Worker* if the hot water heating job, as arranged in the sketch herewith, would circulate and heat satisfactorily. If so, how

THE METAL WORKER

Utilizing Waste Heat.

many feet of radiation should be placed in each room, and how many square feet of surface should be exposed in the pipe coil which is to heat the water? The building is of brick construction and the rooms to be heated have a northern and western exposure. The range has about 2 square feet of surface for heating a 52-gallon boiler and burns coal. What size should the

flow and return mains be? The coil for heating the water would have to be arranged in the second joint of the stove pipe, as shown.

PAINT FOR GALVANIZED IRON.

From the Joseph Dixon Crucible Company, Jersey City, N. J.—In answer to the inquiry of "B. B. C.," in *The Metal Worker* of November 30, we would suggest that the galvanized iron be cleaned of the grease or paraffin oil used in its manufacture. Sometimes the surface is not greasy and special treatment is not necessary. However, the iron is generally found more or less greasy, and this grease can be washed off by a solution of soda or soap and an alkaline solution. After this treatment the surface should be thoroughly washed, and after it is dry the Dixon silica-graphite paint can be applied, with our assurances that it will give a tenacious coating that will not peel, crack or blister.

LIFT PUMPS WITH LONG SUCTION PIPE.

From C. R., Fishkill, N. Y.—I should like to hear, through *The Metal Worker*, from some who have had experience regarding the best way to install lift pumps

Lift Pumps with Long Suction Pipes.

with long suction pipes at the extreme limits of lift, say 15 to 25 feet, when the pipe is 100 feet long. I would ask if air chambers on suction pipes have been found of advantage; also if a check valve on the suction pipe, between the pump and the foot valve at the end of the pipe, is of any benefit when $1\frac{1}{4}$ -inch pipe or larger is used. The sketch herewith gives an idea of the conditions to which I refer.

Letter from the Trade.

CONVICT LABOR COMPETITION.

A New Jersey manufacturer of Hollow Ware, Hardware Specialties, and other Cast Iron Goods writes as follows:

I note that labor organizations are taking strenuous measures in the matter of the Chinese Exclusion act. Is it not strange that a worse menace to labor than either the above or pauper labor should receive so little attention? I refer to the convict labor competition. New York State forbids it except for the use of charitable and other State institutions, and the plan works well. The State, through its representative, has a bill in Congress allowing States to forbid the product of convict labor being brought from States having a surplus of convict labor products. This is designed to save the mechanic from the dire effects of 15 to 25 cents a day jailbird competition. The bill is in a dark recess of some pigeon hole, and for some reason has remained there for several sessions of Congress. What is the reason for this, in view of the promised protection to American labor? Foreign countries do not allow convict made goods within their borders.

Vaseline, to which a small amount of powdered gum camphor has been added, the mixture being heated over a slow fire, is recommended as an excellent preventive of rust on tools.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin declined sharply, dropping about 7c. in price.
Copper is without change and demand light; market somewhat feverish.
Pig Lead is unchanged and quiet.
Spelter is quiet and firm.
Antimony is unchanged.
Nickel continues firm and active.
Aluminum is active at former prices.
Tin Plates are dull, with prices for spot ruling lower.
Sheets are still in active demand and scarce, but prices are softening under influence of competition.
Genuine Russia Iron Sheets are 1c. higher for heavier grades.
Sheet Copper continues firm, with fair demand.
Pig Iron is very firm and Foundry Irons for early delivery are higher.
Hardware continues in active demand at steady prices.
Plumbers' Supplies are still moving in good volume for the season, with prices firm.
Plumbers' Brass Goods are firm and prices are likely to be maintained.
Cast Iron Soil Pipe and Fittings are firm and in good demand.
Solder prices have been reduced about 2c. per lb.
Building Papers are active and prices have stiffened.
Wire Nails are in active demand; prices show some irregularity.
Cut Nails are firm, with some falling off in demand.
Wire is moving freely, with some unevenness in prices.
White Lead is quiet and unchanged.
Linseed Oil is lower.
Spirits Turpentine is strong, with moderate demand.
Old Metals are without change, except for Stove Plate Scrap, which is ½c. higher.

METAL MARKET.

NEW YORK, December 6, 1901.

Pig Tin.—The corner in Spot Tin, which last week shot prices up to extreme figures, is over and prices have again settled back to about normal values. Just before the close of the month the delayed steamers all arrived safely, and, being promptly discharged, relieved the stringency of the situation. Immediately the price of Spot Tin fell rapidly and continued to decline during the week. At the close the decline seemed to have been checked and prices stiffened again somewhat. Jobbers' prices are now about 7½c. lower than those ruling a week ago, small lots of Straits Pig being quoted at 26¼c. to 26¾c. per lb. The monthly statistics are viewed as being very unfavorable. The increase in the visible supply amounts to more than 2700 tons, being the largest for the year.

Charles S. Trench & Co., 81-83 Fulton street, New York, issued under date of December 2 the following review of the Pig Tin market:

During the past month, on account of small stocks and delayed arrivals, the fluctuations in price of Spot Tin have been sensational—opening price, 24.95c.; highest, 33.50c.; lowest, 24.80c., closing very nominal at 29.75c.

Estimated stocks on spot, New York, Philadelphia and Boston, November 1.....	Tons. 1,433
Actual arrivals during November.....	2,125

Estimated consumption during November.....	3,558
	2,100

Estimated stocks on spot, New York, Philadelphia and Boston, December 1.....	1,458
Actual afloat from East Indies, shipments to November 1, due late December.....	585

Actual afloat from East Indies, shipments to November 1, due January.....	2,225
Actual afloat from England, shipments to November 1....	947
Actual afloat from Continent, shipments to November 1...	30
Total visible supply, December 1.....	5,245
As against November 1.....	4,018
As against October 1.....	4,891
As against September 1.....	4,476

The explanation of relatively small deliveries to consumers during the month in spite of the general manufacturing business activity is that for the first 22 days of the month only 530 tons arrived from which shipments could be made, and stocks in store were so small that they were quickly depleted, and prices ruled for the latter part of the month at such excessive premiums over prices at which supplies were offered ex overdue steamers that every effort was made to avoid paying the scarcity price. With Spot Tin during the last ten days or more ruling at from 1c. to 7c. per lb. over which supplies could be obtained ex steamer overdue, and expected to arrive every day, not only have our consumers run down their stocks to nothing, but at least 150 tons were in the last ten days of the month hurriedly shipped back to New York by consumers and sold or exchanged for ex overdue steamers. Of the above 1458 tons, we estimate on spot December 1, not 50 tons is in store, the balance is on dock or in vessels at dock now being unloaded, and fully one-half of the dock amount is pledged to consumers who are clamorous for shipments. With a return to fairly normal conditions the demand for quick shipments will be large during December.

Copper.—It looks as if the crisis in Copper was close at hand. The market is entirely demoralized. The large interest which has upheld the price right along is reported in the trade to be about to give up the fight in this respect and declare an open market. All quotations are entirely nominal and only the most urgent purchases are being made. Small lots of Lake Copper are still quoted by jobbers at 17¼c. to 17½c., and Casting Copper at 16¾c. to 17c. per lb. Rumors of large sales of Copper at cut prices, or at present prices with a guarantee against decline, are discredited in the trade. It is held that, under conditions such as exist to-day, consumers would not enter the market under any circumstances. The course of the London market is taken to reflect the actual situation in Copper. Very large sales have been made there lately at prices equivalent to 12c. It is claimed that Copper could be bought here, refined and laid down at a price not exceeding 13½c.

Sheet Copper.—A fair demand continues for Sheet Copper, with no change in prices, which remain on the basis of 21c. per lb. Consumers, however, are evidently buying more conservatively, in view of the critical condition of the market for the raw material.

Pig Lead.—No change has taken place in the Pig Lead situation here. The market is quiet, and prices remain at the former level. American Pig in small lots is quoted at 4.55c. to 4.60c. per lb. St. Louis advices report no change in that market, a quiet business and the same range of prices ruling.

Spelter.—Business in Spelter is quiet, and prices are without change in any direction. Western brands in small lots are quoted at 4.55c. to 4.60c. per lb. It is reported that the proposed combination of producing interests will not be effected after all. St. Louis advices report considerable activity in the Spelter market at that point, heavy transactions having been effected with prices higher and offerings light.

Sheet Zinc.—The usual demand for Sheet Zinc is noted by jobbers who quote 600-lb. cask lots at 6¾c. per lb., and smaller quantities at 7¼c.

Antimony.—No change has taken place in this metal. Cookson's in small parcels is quoted at 10½c. to 11c., and Hallett's at 8½c. to 9c. per lb.

Nickel.—Is unchanged, prices continuing on the basis of 60c to 65c. per lb. for small lots.

Aluminum.—An active demand for Aluminum continues, and prices remain at 37c. per lb. for small lots of

No. 1 Ingot guaranteed 99 per cent. pure, and 35c. for 100-lb. lots.

Tin Plates.—The Tin Plate market is quiet and uninteresting. Business is of a limited character. The larger consumers appear to have covered their wants for the first quarter of 1902, which is as far as the American Tin Plate Company will make contracts. The smaller trade is quite active for the season, and supplies are somewhat more liberal. In consequence, jobbers have reduced their prices, which now rule considerably below the highest point reached during the late stringency. American Bessemer Coke Plates, IC, 14 x 20, are now obtainable at \$5.25 to \$5.75 per box. Terne Plates have also been reduced in price, and now rule fully \$1 a box lower than a week or two back. A further decline of 4½ pence per box in the price of Welsh Coke Plates took place this week.

A report on the British Tin Plate trade states that the wave of prosperity which has visited the trade during the last two years is now on the ebb. The works which have been restarted have caused the supply to outstrip the demand, and though it is difficult to obtain Plates for prompt delivery, prices for January and onward are considerably lower. Until the end of the year the works in general are pretty well engaged, and several are full till the end of January; but the majority of buyers are holding off.

Sheets.—The coming into the market of three or four of the new independent Sheet mills, which are ready to start and are soliciting orders vigorously, tends to soften the price of Sheets, although it is not yet apparent in the quotations of any of the makers, who are filled up with orders for some time ahead. As a matter of fact, supplies are just as difficult to get as ever, and a considerable scarcity still exists for some grades of Black Sheets. Orders are still coming in very freely, but the pressure that existed lately has relaxed in some degree. The mills are still a good deal behind with their orders, but are slowly catching up. No. 27 One Pass Cold Rolled Soft Steel Sheets are now quoted by jobbers at 4c. to 4.05c., and Galvanized at 65 to 67½ per cent. off the list. There is some scarcity in Genuine Russia Iron Sheets of the heavier gauges, which has caused an advance in the price of that material. Genuine Russia Iron Sheets, in small lots, are now selling as high as 14c. in some cases.

Chicago advices are as follows: There are many orders for Sheets running up into several hundred tons each. Mills do not seem to be gaining upon their orders and are still several months behind. Orders placed last summer are now being delivered. Prices are without change, though ranging more widely than when supply is normal. No. 27 Common is quoted 3.50c. to 3.70c., and Galvanized, 65 and 10 to 70.

Old Metals.—The market for Old Metals is inclined to dullness. Prices, while rather irregular, are without quotable change. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb. 14¾c.
Light and Tinned Copper.....	per lb. 12¾c.
Heavy Brass.....	per lb. 9¾c.
Light Brass.....	per lb. 7½c.
Lead.....	per lb. 4 c.
Tea Lead.....	per lb. 3½c.
Zinc.....	per lb. 2¾c.
No. 1 Pewter.....	per lb. 17½c.
No. 2 Pewter.....	per lb. 8½c.
Tin Plate Scrap, per gross ton.....	\$6.50 to \$7.00
Wrought Iron Scrap, per gross ton.....	10.50 to 11.00
Heavy Cast Scrap, per gross ton.....	10.25 to 10.50
Stove Plate Scrap, per gross ton.....	7.75 to 8.00
Burnt Iron, per gross ton.....	5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—The majority of the furnaces tributary to this district are sold up for from four to six months, and yet the demand is not fully satisfied. There is some disposition among sellers to protect themselves by asking an advance upon present prices on deliveries during the next few months. Among the recent sales we note one lot of 3000 tons to a stove founder, the sellers being Eastern Pennsylvania and Virginia furnaces. We quote: No. 1, \$16.35 to \$17.50; No. 2 X, \$15.65 to \$16; No. 2 Plain, \$15.15 to \$16; Tennessee and Alabama brands,

No. 1 Foundry, \$16; No. 2 Foundry, \$15.25; No. 1 Soft, \$16; No. 2 Soft, \$15.25; No. 3 Foundry, \$14.75; No. 4 Foundry, \$14.25.

CHICAGO.—Melters of Pig Iron in this district have been driven to various expedients to keep their output from impairment in the present Coke scarcity. Some are using Anthracite Coal as a substitute for Coke. Foundrymen have been compelled also to resort to the partial use of off grades. It is not believed that the output of the foundries has been seriously affected by the Coke shortage, although an indefinite continuance of the present scarcity would lead to serious results. Local Irons are considerably stronger, prices being 50c. higher than a week ago. There is a marked reluctance among local producers to sell Iron for prompt or near-by shipments. A moderately large business has been transacted in lots running from 200 to 800 tons. We quote as follows:

Lake Superior Charcoal.....	\$18.00 to \$19.00
Local Coke Foundry, No. 1.....	16.00 to 16.50
Local Coke Foundry, No. 2.....	15.50 to 16.00
Local Coke Foundry, No. 3.....	15.00 to 15.50
Local Scotch, No. 1.....	16.00 to 16.50
Ohio Strong Softeners, No. 1.....	17.25 to 17.50
Southern Silvery, according to Silicon..	16.15 to 16.40
Southern Coke, No. 1.....	15.65 to 16.15
Southern Coke, No. 2.....	15.15 to 15.65
Southern Coke, No. 3.....	14.65 to 15.15
Southern Coke, No. 1 Soft.....	15.65 to 16.15
Southern Coke, No. 2 Soft.....	15.15 to 15.65

PHILADELPHIA.—A fair amount of business was closed during the week, and a great deal more could have been done if makers had held out inducements. Stocks are so much reduced that prompt shipments command extreme figures, as \$16 for No. 2 X and \$15.50 for No. 2 Plain. For the first and second quarters of 1902 it is probable that about 50c. less would be accepted. Meanwhile, makers are protecting their trade by adapting their quotations according to the quantity required, date for delivery, &c. On such a market it is difficult to give exact prices, but the range would be about as follows, the top figures being for early shipments for Philadelphia and nearby points: No. 1 X Foundry, \$16.25 to \$16.50; No. 2 X Foundry, \$15.75 to \$16, and No. 2 Plain, \$15.25 to \$15.50.

PITTSBURGH.—There is not much Iron being sold for the reason that the furnaces are sold up and have no prompt Iron to spare, and also because they cannot get cars enough to ship out the Iron they have already sold. Foundry Iron is very firm, and the furnaces report their product practically sold up for six months. We quote No. 1 Foundry Iron at \$16 to \$16.50, and No. 2 at \$15.50 to \$15.75, Pittsburgh.

CINCINNATI.—There has been but slight change in the general situation. Buying has not been so active as it was before prices were raised two weeks ago, but there has been nevertheless a fair run of orders averaging 200 to 500 tons. This from widely scattered consumers and from nearly all branches of the trade. Sellers are not pushing business and buyers will not be likely to seek much Iron from now until the first of the year, hence a seasonably quiet December is looked for. The great problem for all concerned is the shortage of cars and the difficulty in getting Iron moved is seemingly on the increase. Northern Irons are a little higher. Southern brands unchanged. We quote, f.o.b. Cincinnati:

Southern Coke, No. 1.....	to \$15.00
Southern Coke, No. 2.....	to 14.25
Southern Coke, No. 3.....	to 13.75
Southern Coke, No. 4.....	to 13.25
Southern Coke, No. 1 Soft.....	to 15.00
Southern Coke, No. 2 Soft.....	to 14.25
Southern Coke, Gray Forge.....	to 13.25
Southern Coke, Mottled.....	to 13.25
Ohio Silvery, No. 1.....	\$15.60 to 16.10
Ohio Silvery, No. 2.....	15.10 to 15.60
Lake Superior Coke, No. 1.....	16.10 to 16.60
Lake Superior Coke, No. 2.....	15.60 to 16.10
Lake Superior Coke, No. 3.....	15.10 to 15.60

ST. LOUIS.—Transactions in the Pig Iron market continue along on about the same lines, and the volume of sales foot up to about the same total as for several weeks past. Orders average from 300 to 500 tons each. The Coke transportation situation among the Southern furnaces shows no signs of improvement. We quote as follows for cash, f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$15.50 to \$15.75
Southern, No. 2 Foundry.....	14.75 to 15.00
Southern, No. 3 Foundry.....	14.25 to 14.50
Southern, No. 4 Foundry.....	13.75 to 14.00
No. 1 Soft.....	15.25 to 15.50
No. 2 Soft.....	14.75 to 15.25

CHICAGO REPORT.

Scrap Iron and Steel.—The market continues in a rather unsatisfactory condition. A report is being circulated of an attempt upon the part of some Scrap dealers to corner the market, they holding something like 40,000 tons. Mills are determined to resist the squeeze and have combined to keep prices from being advanced. The situation is interesting and promises to become more so before many days. We quote dealers' buying prices in carload lots, Chicago delivery, as follows:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast.....	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	8.00 to 8.25
Burnt Iron and Grate Bars.....	5.50 to 6.00
Sheet Iron and Hoops.....	6.00 to 7.00
Plow Steel..... to 10.00
Breaking Stock.....	9.00 to 10.00
No. 2, such as Shovels, Hoes, &c..... to 7.00
Old Boilers—whole (Iron).....	6.50 to 7.00
Old Boilers (Iron) cut in single Sheets and Rings.....	9.00 to 10.00
Old Gas Pipe and Boiler Tubes.....	10.50 to 11.50
Cast Borings.....	4.50 to 5.00
Turnings.....	9.50 to 10.00
Horseshoes..... to 13.00

Old Metals.—The demand for Tin Foil continues the feature of the market, and dealers now quote 22½c. Dealers quote buying prices on small lots as follows:

	Per lb.
Copper Wire and Heavy.....	14¾c.
Copper Bottoms.....	13¾c.
Copper Clips.....	14¾c.
Red Brass.....	13¾c.
Yellow Brass.....	9¾c.
Red Brass Borings.....	11½c.
Yellow Brass Borings.....	8½c.
Light Brass.....	7½c.
Pipe Lead.....	4 c.
Tea Lead.....	3¾c.
Zinc.....	2.80c.
Tin Foil.....	22½c.
Pewter, No. 1.....	18 c.
Pewter, No. 2.....	15 c.

Old Rubber.—The market continues as last reported. Rubber Shoes are still quite plentiful and price is a trifle lower. We quote as follows:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7 c.
Rubber Car Springs.....	5½c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	7¼c.
Black Rubber.....	4¼c.
White Rubber.....	8½c.

Rags.—Market is unchanged. Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at .75c. to .85c. per 100 lbs. in any quantity.

Anthracite Coal.—The scarcity in Chestnut Coal continues, as does also the scarcity of cars. Prices are unchanged, as follows:

	Grate.	Egg and Stove.
Chicago.....	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

THE HARDWARE TRADE.

There is a good volume of current business and the trade are evidently buying freely in most lines. Season goods are still commanding the attention of many of the larger merchants and a great many orders have been taken. Prices for Hardware both Shelf and Heavy, are as a rule steady. A few lines are regarded with especial caution as liable to yield something in price before long. A large proportion of the orders coming in to manufacturers are for early shipment to meet immediate wants or to supply waiting customers. Winter goods are in especial demand, and on some lines are developing a decided scarcity. Merchants with the opening of the last month of the year are entering upon preparations for the holiday trade, which promises to be large, in view of the prevailing prosperity and the increasing observance of the holiday season. Merchants who have not completed their arrangements for the Christmas and New Year trade may find it necessary to make special efforts to get some lines of goods in time. Preparation for the closing of the year and plans for the next naturally begin to occupy the attention of manufacturers, but the pressure of current business is still heavy. Questions in regard

to the outlook for the coming year—the continuance of the demand, the price of the raw material, the extent to which foreign trade will be developed—are being canvassed and optimistic views are generally entertained.

NOTES ON PRICES.

Plumbers' Brass Work.—The meeting of the Brass Association, which was scheduled to be held in Pittsburgh, Pa., on December 9, has been postponed. It will be held in Washington, December 11, a day previous to the meeting of the manufacturers and jobbers east of the Alleghany Mountains. It is expected that there will be no change in the prices now prevailing. From what can be ascertained, it appears that stocks of Brass Goods in jobbers' hands are very low, and this condition of affairs is not unknown to the Brass manufacturers. This fact alone should be sufficient to keep the present prices from being broken. Another feature of the Brass trade which will tend to keep prices up is that all of the manufacturers have considerable business now on hand, and, until their old orders are completed, there is no likelihood of a break in values.

Cast Iron Soil Pipe and Fittings.—The association controlling Cast Iron Soil Pipe and Fittings have recently acquired another member. The Birmingham Pipe & Castings Company of Birmingham Ala., have renewed their agreement with the association for another year. We understand that this was the only company who withheld their consent at the last meeting held in New York City, when the prices on Cast Iron Soil Pipe were reaffirmed. The signing of the Birmingham Pipe & Castings Company will materially strengthen the association. Jobbers should now have a stable market for at least a year to come.

Solder.—The sharp break in the price of Tin has been followed by the marking down of prices on Solder, which now rule about 2 cents below the figures of a week ago. Jobbers quote Half and Half, guaranteed, in small lots, at 17½c. to 18c. per lb., and No. 1 at 15½c. to 16½c.

Sheet Zinc, Nickel Plated.—A. Klein, 453-455 Broome street, New York, is the sole agent in the United States for German made Sheet Zinc, Nickel Plated on one side, manufactured by the German Nickel Zinc, Steel and Tin Sheet Factory, Essen, Germany. This Nickel Plated Zinc is used for the manufacture of a variety of specialties requiring a ductile metal not likely to tarnish. Importation orders, are taken f.o.b. Hamburg or Bremen. The material comes regularly in sheets 20 x 20 inches, in cases of 220 pounds, and 20 x 40 inches, in cases of 440 pounds. The following are the current net quotations for import, in German marks (24 cents) per 100 kg. (220 pounds):

Nos.	Gauge in millimeters, exact.	Approximate decimals of inch.	Marks per 100 kilos.
0.....	.050	.002	..
½.....	.075	.003	..
1.....	.100	.004	..
2.....	.143	.0055	98
3.....	.186	.0075	87
4.....	.228	.009	82
5.....	.250	.01	77
6.....	.300	.012	76
7.....	.350	.014	74
8.....	.400	.016	73
9.....	.450	.018	72
10.....	.500	.02	71
11.....	.580	.023	70.50
12.....	.660	.026	70
13.....	.740	.029	69.50
14.....	.820	.032	69
15.....	.950	.038	68.50
16.....	1.080	.04	68
17.....	1.210	.05	68
18.....	1.340	.052	68
19.....	1.470	.056	68
20.....	1.600	.063	68

Nos. 0, ½ and 1 can be made, but for ordinary use are too thin. This material, if necessary, can be supplied with both sides nickeled.

Building Papers.—The business in building papers is very good, and, as predicted some time ago, prices have stiffened somewhat. Manufacturers of Rosin Slized Sheathing, we are credibly informed, have recently agreed on a uniform price, which shows an advance over previous quotations of \$2 to \$3 a ton, the price in round lots being now \$25 per ton. By the roll, light, medium and heavy weights are quoted 32, 47 and 58 cents per

roll, respectively, equivalent to about \$32, \$31 and \$29 per ton, which is a delivered price. Deafening Felts, 9, 6 and 4½ square feet to pound, have been advanced to \$40 to \$42 per ton, an upward movement, however, that always occurs at this season of the year from the nature of the product. In Tarred Roofing Felt, one ply, the price has been advanced to \$28 to \$30 per ton, current prices on the two and five ply goods, remaining at 40 to 45 cents and 60 to 65 cents per roll respectively. This has been occasioned by an advance in the price of paper for the Saturated or Tarred Roofing Papers, which, in large lots to jobbers, is now \$38.50 per ton.

Wire Nails.—The continued demand for small lots of Wire Nails from store aggregates a considerable volume. Lower prices are reported as being made by outside mills. The influence of this competition is naturally in the direction of a reduction in prices, but the market is steadied to a good degree by the strength in Rods and Billets, which justifies the maintenance of the price of Wire products at a point not much below the present level. Small lots of Wire Nails from store, New York, are quoted at \$2.35 to \$2.40 per keg.

Cut Nails.—The near approach of prices at which Wire Nails can be purchased to Cut Nail quotations is causing a falling off in the demand for the latter. The Cut Nail market, however, is firm, small lots from store, New York, ruling at about \$2.25 per keg.

Wire.—Makers of Poultry Netting and other Wire products are placing liberal orders in anticipation of an active demand for the coming spring. There is some unevenness of prices, small lots of Plain Wire, New York, being quoted at about 2.55c., and Galvanized at 2.95c.

Window Glass.—The local Window Glass market remains in about the same condition as last week. The demand is light, with prices ranging from 90 to 90 and 5 per cent. discount.

White Lead.—The market for White Lead in Oil has been quiet and featureless. The outlook for the future is viewed with a good deal of confidence by the trade in general. In a retail way, White Lead in Oil is selling at 7 to 7¼ cents per pound.

Spirits Turpentine.—The local market is strong, owing to favorable reports from the South. The demand here is limited, with prices firm. Moderate sized lots from store are quoted at from 38½ to 39 cents per gallon.

Old Rubber.—A fairly good business is noted, and prices are well maintained, except for Rubber Shoes, which rule lower. Dealers in New York and vicinity are paying about the following figures:

Car Springs, ton lots, per lb. 5¼c.
Rubber Shoes, less than carloads, per lb. 7 to 7¼c.
White Wringer Rolls, per lb. 7½c.
Inside Bicycle Tubing, per lb. 21½c.
Outside Tubing, per lb. 7c.

TRADE NOTES.

F. W. DEVOE & Co., New York, are distributing a neat folder calling attention to their Pure Lead and Zinc Paints, which they state are strictly pure and free from all form of adulteration. These Paints are sold ready for use without any further mixture.

In our advertising columns this week appears a notice from Blake & Andros, manufacturers of B. & A. Elbow Valves and Kerosene Heaters, 28 Portland street, Boston, Mass., offering showroom space in a central location in that city, wherein they are prepared to represent one or more specialties in addition to their own established business.

THE NEW YORK METAL SPECIALTY MFG. COMPANY of New York City have been incorporated with a capital of \$10,000. The directors are A. W. Hoffman, Philip Harnischfeger and Adam P. Dienst of New York City.

"A TREATISE ON THE PRESERVATION OF METAL" is the title of a little book by Lionel M. Stern of Cleveland, Ohio, written in the interest of all who require a coating on metallic surfaces for their preservation.

THE JOSEPH DIXON CRUCIBLE COMPANY of Jersey

City, N. J., are sending out a small calendar blotter for December in the interest of Dixon's American Graphite Pencils.

Changes in Mexican Customs Tariff.

The President of the republic of Mexico has issued a decree instituting certain changes in the customs tariff of that country. Among the changes we note the following in which our readers are interested:

Tin in bars or in bulk.....	Per gross klllo.	\$0.12
Lead in bars or plgs.....	" " "	.03
Lead goods, not otherwise specified.....	" " "	.08
Lead in sheets or piping, and glaziers' lead..	" " "	.05
Manufactured goods of tin, tinned or nickel plated iron, either wholly or in part, not otherwise specified.....	" " "	.20
Iron or steel ware, enameled either wholly or in part, not otherwise specified.....	" " "	.15
Nails, screws, bolts, nuts and rivets, of iron or steel.....	" " "	.10
Tanks, cisterns, receptacles or vats of iron or steel, with more than 2500 liters capacity	" " "	.01
Iron or steel wire cloth of all kinds.....	" " "	.10
Suction and force hand pumps, with spare or repair pieces.....	" " "	.01
Emery in powder or grain.....	" " "	.01
Black plumbago.....	" " "	.05
Paints in powder or crystals.....	" " "	.07
Prepared paint.....	" " "	.12
Tiles, ridge boards and ventilators of clay for roofs, and drain pipes of clay, per 1000.....		2.50

The decree became effective November 1, 1901.

PERFORATED METALS

STEEL, IRON, COPPER, ZINC, BRASS, TIN, and all other metals
PERFORATED AS REQUIRED for

Grain Cleaning and Mining Machinery Woolen, Cotton, Paper and Pulp Mills, Rice,
Flour and Cotton Seed Oil Mills, Sugar and Malt Houses, Distilleries, Filter Presses,
Stone, Coal and Ore Screens, Brick and Tile Works, Filters, Spark Arresters, Gas
and Water Works, Oil, Gas and Vapor Stoves, Coffee Machinery, &c., &c.

Standard Sizes Perforated Tin and Brass Always in Stock.

The Harrington & King Perforating Co.,

"BOSS" WASHING MACHINES.

Trade-Mark.

Closed View.

Illustration of the latest improved "BOSS" double action and rub board washing machine. Has all gearing enclosed and other important improvements.

SIZES: { 7, 8, 9, wood frame lower cylinder.
10, 11, 12, steel frame lower cylinder.

We are also the patentees and manufacturers of the following:

The Boss Internal Gear Washer,
" " External " "
" New Boss Rotary " "
" " Champion Rotary " "
" " Standard Champion " "
" Standard Perfection " "
" Banner Washer and
" Improved Standard.

The washers are carried in stock in carload lots in all the principal cities. Write us and we will quote you prices and at same time advise you as to where and from whom you can obtain them from stock, thereby, perhaps, saving extra cost of freight, than when shipping from factory. These washers are carried in stock under jobbers' special brands, but none are genuine without our name and address appearing on each machine. Write for one of our beautifully illustrated and descriptive catalogues, mailed free upon application.

TINSMITHS' HELPER *and* PATTERN BOOK

WITH USEFUL RULES,
DIAGRAMS and TABLES
= By H. K. Vosburgh =
NEW AND IMPROVED EDITION

A USEFUL hand-
book for tin-
ners and other
mechanics, treat-
ing simple prob-
lems in pattern
cutting, such as
are of daily occur-
rence in the shop.
An elementary
manual for the
young tinsmiths.
A handy reference
for all sheet metal
workers.

120 Pages
53 Figures

An Invaluable \$1.00
Pocket Companion . .

Section 1 ~ Pages 1-66 Diagrams and Patterns

Demonstrates in a simple way, and by means of illustrations and descriptive text, about 50 examples of sheet metal pattern work, such as the method of cutting can breasts, flared tinware, scale scoops, oval boiler covers, lips for measures, elbow patterns, &c.

Section 2 ~ Pages 69-88 Epitome of Mensuration

Compiled with regard to the requirements of the tinner, describing how to find the area of a circle, the circumference of a circle, the contents of a sphere, a cylinder, a cone, and other information relating to the work of a tinsmith.

Section 3 ~ Pages 89-120 Tables, Rules, Recipes

Gives tables of the weights of sheet metals, including the weight of black sheet iron, sheet lead, and galvanized iron sheets with their dimensions; the weight of lead pipe per foot; the weights of tin plates, sheet copper and sheet zinc. Several pages are devoted to tables giving the areas and circumferences of circles, the capacity of cans, the number of barrels in cisterns and tanks, sizes of tinware in form of frustum of a cone, &c., and practical receipts, including mixtures for solders of different kinds, soldering fluxes, and various cements.

Domestic Electrical Work.

Concise and Practical Explanations for Plumbers, Tinnerns and Hardware Dealers on How to Wire Buildings for Bells, Alarms, Annunciators, and for Gas Lighting from Batteries.

Illustrated with Twenty-two Diagrams.

By **WILLIAM A. WITTBECKER.**

Price in Paper, 25 Cents.

Price in Cloth, 50 Cents.

The growing demand for simple electrical apparatus in dwelling houses, offices and workshops, and the need of plain instructions whereby any person without a previous knowledge of electricity may be enabled to undertake their successful installation, has prompted the publication of this little book. It is not intended for the amateur who seeks for nothing but experimental work, neither is it expected to enlighten the expert electrician; but to the person who is seeking for information that will assist him in increasing his daily earnings this little volume is addressed. The information given is above all else practical, and with a close observance of the directions laid down any one without the slightest knowledge of electricity should be able to to the work described.

A UNIVERSAL REMEDY FOR LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 600 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails. In 5, 10 and 15 lb. Pails.

Galvanizing and Tinning.

A Practical Treatise on Coating with Tin and Zinc, with a Special Chapter on Tinning Gray Iron Castings. By W. T. Flanders. Size 5½ x 8 inches. 98 pages, 40 illustrations. Cloth bound. Price \$2.00.

The author of this work has made a specialty of galvanizing and tinning, and has been employed to erect plants in various parts of the country, also to instruct the owners, so that, in all instances, they have been able to operate them successfully. The subject of galvanizing is, therefore, treated from the standpoint of an expert and in a practical manner. The selection of materials and apparatus for erecting plants of large and small capacity is treated, together with instructions for their equipment and accompanied by many illustrations of the plants and of the tools and appliances. Plain directions are given for the preparatory treatment of metals and articles to be coated, and every detail which is of importance in successfully applying to metals a secure and attractive coating is described. The tinning of articles is treated in the same practical manner. The difficulties found by many who have attempted to tin malleable and gray iron castings are explained and methods for doing the work made simple.

CONTENTS.

Galvanizing.

Locating a Plant and Selecting a Kettle.
The Galvanizing Room.
Tanks for Acids and Other Purposes.

ART
IN
Metal Ceilings
MOORISH DESIGN.

Moorish is the style of design originated by the Moors of Northern Africa and of Spain.
It is entirely devoid of representation of animal life and nearly so of vegetable forms.
It is especially rich in geometric interlacings.

Our " ***Classik*** " BERGER'S
TRADE MARK
METAL CEILINGS

is an excellent example of this class, and is especially well suited for decorating interiors finished or furnished in Oriental Style.
Write for details.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting
as applied to all branches
of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection
of 218 problems and an elaborate
explanation of the principles of
pattern cutting, including Triangu-
lation.

It embodies the problems of the
former Metal Worker Pattern Book,
all of which have been revised, and
many of which have been entirely
rewritten and solved by more ap-
proved methods. To these have
been added 75 new problems and
much other new material and ex-
planatory matter, making this work
a model of completeness in every
respect.

ARRANGEMENT.

In point of arrangement the new
work far surpasses the former one
in that the problems are classified
under three different heads, and
simply indexed, and also that by
means of a table of contents any
required department of the work
can be easily found.

CONTENTS.

While Chapter VI, comprising the
greater part of the work, is devoted
to the solution of problems, the
five preceding chapters thoroughly
explain the principles of pattern
cutting, and place the student in
possession of the preliminary infor-
mation necessary to a thorough
understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials
—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUT-
TING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)
—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tanners, Cornice Makers and
Sheet Metal Workers should be
provided with a copy of

THE ELECTRIC CITY GUTTER FORMER.

The Electric City Gutter Former can be bought for 50 per cent. less than other machines intended for the same purpose. This machine will do everything that can be accomplished by any other gutter former. No other machine can do better work. No other machine can do quicker work. The principle of this machine is entirely different from any other. It is more practical. Both the bead and the gutter are formed in one continuous operation. You do not waste any time in getting the body of the gutter in proper shape. Every operation is mechanical. Each length of gutter is formed exactly alike. No other machine is as practical in its operation. No other machine will give as much satisfaction. The low price is very attractive. The machine will perfectly demonstrate our claims. Ask us about it. We gladly furnish information and price on request.

THE DOUBLE TRUSS CORNICE BRAKE CO., - 1453 Niagara St., BUFFALO, N. Y.

Our Improved Double Truss Cornice Brake is the most practical machine of its kind in the market. Let us send you a description of its merits. Our "latest" has a double edge on front leaf for making fine members and corrugations.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No. 12 gauge, cut wire or bar-steel $\frac{1}{8}$ inch thick, cut off and mitre angle iron $\frac{1}{8}$ inch thick, and do it perfectly.

PRICE, - - \$35.00.

★ SAWS ★

Our Star Hack Saws are now used in nearly all Iron-working Shops the world over. They are equally useful for farmers and men in all departments of life. They will cut iron and wood equally well. A nail does not dull them at all. One blade, which costs five cents, will cut off an inch square bar of iron 200 times without sharpening. We have cut off such a bar 387 times with one blade. All hardware dealers will furnish these saws. If not, we will send one steel frame and six blades by mail, prepaid, on receipt of \$1.00. All good blades are stamped with a ★

Excelsior Point No. 3.—VENTILATED OVEN.

On the oven door of every Excelsior Range there is a ventilating register by means of which fresh air is admitted into the oven. The oven also has openings into the flue. This arrangement admits enough fresh air into the oven to keep the roast from drying up, thus preserving the juices of the meat. This idea is not carried to excess, and the oven is ventilated into the *flue* and not into the *kitchen*. That's another good point.

Sheep Tails and Heater Tales.

Abe Lincoln once asked: "If you call a sheep's tail a leg, how many legs would it have?" "Five," came the reply. "Wrong; it would have no more than four; calling a tail a leg does not make it one." A given amount of fuel gives a certain amount of heat. We realize this, and build our heaters accordingly. We might rate an apparatus built to do a certain amount of work at 20, 30 or 50 per cent. more. But giving it that rating wouldn't make its capacity any greater. A heater can't do more than it can and it doesn't pay to tell fairy tales about heating capacities.

READ OUR OFFERINGS.

Special Advantages Over All Other
Heaters.

OUR HEATERS are only 4 ft. 3 in. high, giving excellent elevation for Hot Air Pipes.

OUR HEATERS ARE ALL CAST IRON, no repairing of sheet iron drums necessary every few years.

OUR MANIFOLD TUBES are steel, $\frac{1}{8}$ inch thick, and will wear for a lifetime.

OUR HEATERS are supplied with the most modern grates, perfect dumping and shaking. Each bar can be separately replaced.

OUR HEATERS are so arranged that they can be perfectly cleaned by any one, and in a few moments.

Equally Efficient with Hard or Soft Coal.

Our Heaters save the heat others waste up the chimney and send it through the house, therefore reduce coal bills.

The Stanton Seamless Heater,

PORTABLE CASED.

LOUISVILLE, KY., Apl. 5th, 1901.

THE STANTON HEATER CO.,
 Martin's Ferry, Ohio.

Gentlemen:—Your favor of the 3d inst. is received asking our experience with the Stanton Heater which you put in for us during the fall of 1899. In reply we will say that it gives us pleasure to express our entire satisfaction with this Furnace. While we have had no severe weather this winter there have been several quite cold snaps, but our offices have been very comfortably heated, and our coal bill (Pittsburgh coal) has been quite moderate compared with other Heaters we have used.

The satisfaction the Heater has given us can be best expressed by saying that we have not heard the Furnace mentioned once this winter. You can see, therefore, that we have had absolutely no cause for complaint.

Yours very truly

ROBINSON-HUGHES & CO.

See our advertisement next week.

Even members of the same family are not always alike in virtue or ability, yet the

Gurney Heaters

Are of uniform excellence. In all of them the heating surfaces are so arranged as to produce a maximum of heat from a minimum amount of coal.

All are made from the best grades of iron, have the most efficient types of grates, and embody all the latest improvements. "Bright Idea," "Doric," and "400 Series" Steam and Hot Water Heaters are thus equipped. Sales of any of them will enhance your reputation. Would you become an agent? Let us hear from you.

WIRETON HEATING CO.,

Main Office and Works, Blue Island, Ill. Chicago Office, 40 Dearborn St.

A Marvelous Seller.

Will automatically turn on the draft of any furnace, steam or hot water boiler

FOUR YEARS AGO in a town not over a hundred miles from Boston, a man had a No. 21 "DIGHTON" put into his house to heat Front Hall, Sitting Room, Dining Room on first floor and three chambers and Bath Room on second floor: he told a friend who completed a house in the Fall of 1900 that he believed the "DIGHTON" was the best and most economical Hot Air Furnace ever built and advised him to get one, as he burned only a few hundred pounds over five tons of coal and kept a coal fire from the first of November until the middle of the following May.

We had an opportunity to talk with the friend a few days ago and he reports equally as satisfactory and economical results and tells us of three of his neighbors who have recently had "DIGHTONS" installed by a local dealer.

In over thirty years' experience in making and selling all types of Furnaces, we never sold an equal number of any one kind and had as little complaint.

No Furnace Manufacturer can now or ever did give the real Furnace value that we do at the price we sell you the "DIGHTON."

You can't afford not to know about it.

A complete line of salable sizes at salable prices.

About Fire Pots.

We formerly lined our fire pots with cast iron—
then they cracked and warped. Now we use fire
brick for lining and will guarantee it for five years.
The lining is replaced through the fire door.

The AMERICAN FURNACE is made strong in
places where other furnaces have proven weak; it is
made of heavy steel and riveted tight like a boiler.
Will burn any kind of fuel.

You can only build up a permanent furnace busi-
ness by handling a first-class furnace. We manu-
facture for the better class of trade.

NEW ERA RADIATOR

HOT FACTS—of which this is No. 3.

Because heated air rises, it is not right to presume that most of it can be caught by cross tubes that intercept its course. To prove this, put your finger **ACROSS** the chimney of a lighted lamp. It burns—that's the horizontal tube. Then put your finger **DOWN** into the chimney, if you dare—that's our perpendicular tube.

This proves that to get most of the escaping heat, the tubes must be placed in the direction of the heat's course. That is why a New Era Radiator secures more heat than any other. You are selling the wrong radiator until you get hold of the New Era. Send for our inducements.

This edition contains besides the two original articles on joint wiping, by experts, a selection of letters and articles on various important phases of the subject

These include the following :

- Joint Wiping on Copper Pipe.
- Wipe Joints on Brass and Iron.
- Wiping Joints on Tin Pipe.
- Wipe Joint on Lead and Iron Pipe.
- To Make Tight Joints.
- Froze the Pipe to Wipe a Joint.
- Wiping Joints Without a Furnace.
- The Effect of a Jar on a Hot Wiped Joint.
- What Caused the Joint to Break ?
- Strength of Joints in Lead Pipe
- Good Wiping Solder.
- Durability of Coarse Solder.
- Plumbers' Paste.
- Cleaning Solder.
- What Breaks Wiped Joints ?
- Hard Solder to Resist Ammonia.

The first article in the book is written by a practical plumber, and is illustrated from photographs representing the hands and tools when wiping joints in various positions. The second, by an expert joint wiper, is also illustrated from photographs and will prove of great assistance to learners. Ample instructions are given on preparing the pipes previous to wiping the joints, with full descriptions of all tools and appliances used. The pamphlet, in short, gives all the assistance that description of the work can furnish and is the most practical and complete account of joint wiping that is published.

Iron Production Still Increasing.

The monthly statistics of pig iron production printed by *The Iron Age* show that there was a further increase in the capacity of the blast furnaces in operation during the month of November, and that we entered December with another record breaking capacity. The weekly capacity of 266 furnaces in blast on December 1 was 324,761 tons, as against 320,824 tons on November 1. It is noted, however, that during November the actual product was not as great as the capacity working fore-shadowed. Quite a number of furnaces were idle for days and weeks at a time for lack of coal, and the returns of actual individual output showed a falling off from the normal. The tonnage thus lost is estimated at not less than 100,000 tons for the month. This probably helped in reducing stocks, which are now low, amounting to only 223,562 tons on December 1, a falling off of nearly 50,000 tons for the month. As an offset to the fact of this reduction, however, it must be taken into consideration that with some furnaces the stock on hand was increased from the current make, simply because it was impossible to get enough cars to ship to consumers, who were clamoring for material. These latest statistics furnish additional proof of the tremendous consumption of iron and steel that is going on. We are now producing pig iron at the rate of 16,850,000 tons per annum, as against the maximum record of 13,789,000 tons in 1900, and yet the little stock of iron now being carried is constantly being drawn upon. That such a condition of affairs has not led to a radical advance in prices of iron speaks well for the self restraint and good judgment of the manufacturers.

American Industrial Progress

The remarkable industrial progress made by the United States in the last few years has frequently formed of late the text for interesting utterances by foreigners, and more particularly traveled Englishmen, who have gained personal experience of the subject at first hand in visits to this country. Among the latest of those who have taken back with them lessons and experiences which they have imparted to their countrymen is Sir John Leng, a distinguished Scotch Member of Parliament, who delivered a rather striking address the other day on the subject of American industrial progress before the Dundee Institute of Engineers. He attributed the growing industrial and commercial supremacy of the United States largely to the fact of the alertness of the

American in adopting anything that is new, provided it seems to possess merits which make it in any way superior to the old. The American, he explained, is not afraid to make experiments; whereas the Britisher sticks to his old methods and ways until he is thoroughly convinced, through the experience of others, that the new is indisputably superior to the old. John Bull is constitutionally conservative, and his creed, as quoted by Sir John, is, "As it was in the beginning, is now, and ever shall be." This quality of his make up is the thing that prevents him from keeping abreast of the modern procession and retaining his former leading place in the ranks of industrial progress. The speaker referred to, in the course of his address, strongly urged upon his hearers the necessity of cultivating open minds and of applying themselves to their work in such a spirit that new ideas, new ways of doing things and new methods and appliances would be likely to suggest themselves. At the same time the whole tone of his remarks disclosed the conviction, latent in his mind, that the start taken by the United States in the industrial and commercial field was too great ever to be caught up with by their Old World competitors. In short, the latter are already badly overdistanced and can only hope to keep a place in the rear of their transatlantic cousins, whose quick intellects and promptness to adopt that which is new and better have already placed them in an unassailable position in the world's industrial progress.

Boilers and Radiators.

During the year a feeling has grown in the heating trade that the contracting steam fitter, as well as the boiler manufacturer, has derived substantial benefit from the frequent meetings which the manufacturers have held, and a confidential relation has been built up which has largely removed any prejudice that may have been felt earlier against these meetings. The effect, so far as boilers are concerned, has been that prices have ruled remarkably firm throughout the year. This fact lends special interest to the recent meeting of the manufacturers of heating boilers and radiators. It was quite generally known that some effort was being expended to formulate a plan for marketing boilers for the coming year on a basis that would be acceptable to all concerned. It is a quite generally accepted report that at this meeting an adjustment of the inconsistencies which heretofore have existed in the prices of various styles and kinds of boilers was effected, and that the changes in price were so slight as to be of little general interest. It is further reported that a policy was decided upon of endeavoring to make the new prices, which are practically the same as those now ruling, hold throughout the year. The opinion is freely expressed that it would be of benefit to the steam fitters throughout the country if they could feel certain that when they submitted an estimate and received a contract for work in the early part of the year, they could purchase the requisite boilers, when needed, at the prices ruling at the time their bid was made. They could also materially aid the manufacturers by placing the orders for the necessary boilers as soon as their contracts were

closed, thus enabling the manufacturers to know early in the season, to some extent at least, what demands for goods are likely to be made upon them.

While this is an important incident of the recent meeting, an equally important feature was the agreement said to have been reached by the manufacturers of radiators to adopt a similar course. During the past year there have been some apparently unnecessary fluctuations in the price of radiators and it is doubtful if the result was profitable to either the manufacturer or the contracting steam fitter. Any profit that may have resulted from these changes has probably gone into the hands of middlemen. While a fluctuating market may have advantages for the shrewd buyer who can give it careful attention, a stable market is far better suited to the majority of buyers of boilers and radiators, who, in all probability, will welcome the efforts of a number of the manufacturers to establish a market at this time of the year, which can be relied upon to hold for all orders which are placed with them. If those steam fitters who favor the policy outlined should support the manufacturers by placing all orders they secure as soon as received, they would confer upon the latter the substantial benefit to be derived from an advance knowledge of the demand that will be made upon them.

Business Methods.

The present tone and tendencies of business emphasize the importance of houses, whether in the manufacturing or merchandising branches of the trade, having and maintaining a high standard of business methods, not only in the management of their internal affairs, but also in the relations with the trade at large. It is, perhaps, inevitable in connection with the growth of establishments or the consolidation of many into one that there be, as we have before pointed out, more or less of the elimination of the personal relation between the sellers and the buyers of goods, but with this there should be an increased promptness and efficiency of service and careful attention to all the details of correspondence. Shortly after the organization of some of the great consolidations in which our readers are interested there was much complaint at the dilatory and unbusinesslike attention given to letters, and even to telegrams, thus increasing unnecessarily the difficulties of trade and adding to its wear and tear. Our readers will remember the protest which was raised against the practice, for which some excuse was found because of the practical difficulties of establishing and working the entirely new system which was requisite in view of the bringing together of a number of widely separated plants and under new trade conditions. The grounds for complaint on the part of the merchant have, however, in very large measure been overcome, and most of the consolidations take their place among the best conducted concerns in the trade.

An illustration of the spirit which is prevailing among them is given in the case of one corporation who make a point to conduct their correspondence on what they term the quick order; in the matter of making quotations or answering general letters it is a rule that their entire mail be disposed of on the day received. Where they find it necessary to get information from any of their factories their system is to have the local manager of that factory, who is thoroughly qualified for the position and understands the art of correspondence and business usage and proprieties, reply to the customer direct from the factory. When they must reply to telegrams they telegraph the factory concerned by code, and the factory

in turn telegraphs their customer fully in reply to his inquiry. Such a policy and the satisfactory service which results from it cannot fail to be appreciated by the trade. It will doubtless as a rule be found that a successful house which occupies anything of a prominent position in the trade has won its position and extended its business largely by the attention given to rendering its customers the best service in matters of this kind.

The principle under consideration applies obviously to merchants as well as manufacturers, and to the small as well as to the large houses, in proportion as they are brought into contact with the trade through correspondence. If there is reason for criticism on account of any lack of attention to this matter by large manufacturers, there is doubtless more ground for it in connection with the business methods of merchants occupying a narrower field and a less important position. The great houses almost necessarily have good methods and are characterized by care and promptness in their dealings with the trade, but with many merchants, who succeed indeed in making a living, there is sluggish movement and slipshod methods. With alert management, promptness in all relations with their trade and careful attention to all details of inquiries there would be a strengthening of their hold on their customers and a constant increase in their number. It is in direction of matters of this kind that personality will continue to assert itself and business ability to conquer success.

Editorial Notes.

A somewhat remarkable tribute to American oil is involved in a recent cable dispatch from London, to the effect that the District Railway of that city has issued an order that the use of American oil be discontinued everywhere on their line, except for office and signal lights. The reason given for this exception is that the American oil does not smoke the lamps. Presumably the order in question was given in the interests of the Russian oil refined in Scotland, but the admission made in the exception referred to is rather calculated to encourage British consumers in the use of the smokeless American product in place of the smoky home made oil.

The sheet metal manufacturers of Chicago are confronted with conditions which appear to threaten labor difficulties. The Amalgamated Sheet Metal Workers' Union have recently been endeavoring to secure an agreement with the Sheet Metal Manufacturers' Association, covering a scale of wages and providing for certain working rules. The employers were willing to pay a minimum scale of wages of 42½ cents an hour for all construction work, but reserved the right to give any scale to workmen sent outside of Cook County. The union have rejected this arrangement, and have demanded a straight scale of 42½ cents an hour. The officers of the union claim that they have received assurances from some of the contractors that the latter would sign individual agreements rather than have work stopped. It is expected that a number of others will refuse to make such an agreement, and therefore it will not be surprising if strikes should be declared against those refusing, and such work as they now have in progress be tied up. The union have had no agreement with the employers since the lockout in 1900, and are now of the opinion that they are sufficiently strong to endeavor to carry their point, but it remains to be seen if this can be done. Among the ranks of the employers are a number of resolute individuals who are not disposed to yield what they consider are their rights.

Meeting Between Capital and Labor.

A meeting of importance to the cause of conciliation between capital and labor will take place next week in New York City in the first annual session of the Industrial Department of the National Civic Federation. This body is already beginning to exert a marked influence in the settlement of disputes between labor and capital. Its aim is to urge upon employers and employed the adoption of the principle of conciliation and arbitration as the best means of preventing strikes and lockouts. What is known as the Conciliation Committee of the Federation was successful last summer in bringing several strikes to a settlement by its intervention. Capitalists, employers and workingmen are all greatly interested in the coming meeting, which will be held in the rooms of the New York Board of Trade and Transportation, 203 Broadway, on December 16 and 17. Among those who are announced to take part are representatives of many organizations of employers, railway associations and heads of large corporations and officials of the leading labor organizations. The principal topics to be discussed will be "The Effect of Machinery on Labor," "The Shorter Hour Movement" and "The Joint Agreement Method of Preventing Strikes and Lockouts." A permanent executive board will be selected and the scope of action and method of future procedure of the National Civic Federation will be decided upon. Among those who are expected to take part are such men as President Charles M. Schwab of the United States Steel Corporation, Senator M. A. Hanna, Abram S. Hewitt, Charles A. Moore of Manning, Maxwell & Moore, New York; William H. Pfahler of the Abram Cox Stove Company; H. W. Hoyt, president of the National Founders' Association; William H. Sayward, secretary of the National Builders' Association; Herman Justi, commissioner of the Illinois Coal Operators' Association; Samuel Gompers, president of the American Federation of Labor; President John Mitchell of the United Mine Workers; James O'Connell, president of the International Association of Machinists; President Theodore Shaffer of the Amalgamated Association of Iron, Steel and Tin Workers; Martin Fox, president of the Iron Molders' Union; Bishop Potter of New York; Archbishop Ireland of St. Paul, A. C. Bartlett of Hibbard, Spencer & Bartlett, Chicago; United States Labor Commissioner Carroil D. Wright, and many others.

Dun's Index Number, covering 350 quotations on commodities was \$101.37 on December 1, being an increase of 3.7 per cent., as compared with November 1, and 11 per cent. over December 1, 1900. This means that the cost of living has increased 11 per cent. in the past year. The general level of prices is now at the highest point in many years. These price records are compiled by *Dun's Review* by multiplying the quotations of all the necessities of life by the per capita consumption. Thus if a man purchased his supplies for one year on December 1 on the basis stated they would have cost \$101.37, while the same quantity of the same article would have aggregated only \$72.45 on December 1, 1897, the lowest point on record. They would have cost \$121.75 on January 1, 1860, when prices were the highest on record.

The export figures for the ten months ended October, just made public by the Treasury Bureau of Statistics, show that the exports of copper from the United States fell off in the period named about \$23,000,000, or 45 per cent. in value, below the exports in the corresponding months of 1900. The falling off is due largely to industrial depression and the consequent reduced demand for copper abroad, as well as to the increased production of copper in other countries and the reduction of price by foreign producers. Our copper exports, so far this year, have been the smallest in five years past, and the foreign demand seems to be declining from month to month. In quantity the falling off in the exports of copper was from 300,160,000 pounds in the first ten months of 1900 to 162,728,000 pounds in the corresponding months of 1901.

THE WESTERN STOVE TRADE.

The Western stove trade has settled down to the usual quiet condition which prevails in the closing month of the year. Reports from numerous manufacturers show a satisfactory volume of business for the year. The month of November witnessed quite a good demand, the trade in heaters having practically come up to expectations. In the vicinity of Chicago the demand for heating stoves during the fall months was very good, probably better than for some years. The generally prosperous condition of the people, particularly of the wage earners, enables them to add materially to their comforts and this has operated to the benefit of the stove trade.

The dealers in the city and its vicinity were conservative in their purchases, and it is gratifying to learn that they have quite generally been able to dispose of their stock and will have very few heaters to carry over to another season. Reports from rural districts indicate that in some cases dealers have been oversanguine and laid in a stock somewhat larger than their trade required. This will account for an occasional note of discord heard in the general chorus of satisfaction with the condition of trade. It is probable that the stove dealers who are also hardware merchants have in some instances been influenced in their purchases of stoves by the excellent demand for hardware. The hardware trade has seldom been so active as during the last half of this year. This was largely due to the great activity in building operations, but partly to the prosperous condition of farmers, who felt warranted in making improvements which involved the consumption of a great deal of hardware.

Manufacturers appear to have suffered very slightly from any disposition by the trade to cut prices. Practically no complaint is heard on this score. It seems that the volume of business was large enough to enable the current production to be satisfactorily marketed, and consequently no pressure was exerted to move goods.

The outlook for the future is considered decidedly encouraging. The fact that dealers have so generally disposed of their stove stocks and are showing themselves to be in prime financial condition by promptly paying their bills, together with the undoubtedly good condition of the country indicated by the general employment of workingmen at good wages, can be taken as an excellent foundation for the belief that the future can be depended upon to continue the good trade which has been experienced this year. Some of the manufacturers are so confident that they are beginning to predict that the coming year will witness a much heavier trade in stoves than the year just closing, provided, of course, that nothing occurs to unsettle the present satisfactory financial condition of the country.

The Late Leonard J. Huking.

Leonard J. Huking, who died in Brooklyn last week, was formerly in the employ of Abendroth Brothers as bookkeeper and salesman, but of late years had been with the Abendroth & Root Mfg. Company. Mr. Huking's death and that of John Frazer Mills of Abendroth Brothers were both published in the papers at the same time. Huking and Mills were always part and parcel of the Abendroth family, and it is one of those coincidences that both should die together. Huking was a very popular man in the stove business in the seventies. He spoke German, Spanish and English equally well, and was a man of education.

In the early seventies he was superintendent for the Abendroth Bros., a water company, established at Carson Sink, Nev. Fifteen men went there with him, 14 of whom died violent deaths. While there he established a Methodist church and Sunday school, and was protected from insult and injury by the miners. During this time he never carried a pistol, depending for safety on his moral influence. He remained at Carson Sink for two years, and the story of his experiences there was thrilling. During his stay there, though often threatened, he would never treat to a wrink. He won the favor of the miners by his care for the sick and helpless.

DISCREPANCY IN PROPORTIONING PIPES.

BY COMPARISON.

Some furnacemen may not have examined as carefully as I the article on "Warming a Chapter House," which appeared in *The Metal Worker* of November 9. If they had done so they would have noted the considerable discrepancy in the proportions between the hot air pipes and the space heated in some of the rooms. A study of the table that would induce an effort to discover the cause could not but prove beneficial. For instance, it would be seen that the proportion between the area of hot air pipe and the space heated in the halls is 1 to 123, while the proportion of the chapter hall on the fourth floor is 1 to 45, and of the small bedroom on the third floor is 1 to 20, and of the bathroom is 1 to 9. The natural inference might be that the pipes are too small in some instances and too large in others. Owing to the large amount of space in the hall it would seem that a larger pipe would be necessary for heating. It is no surprise to me, and probably not to many of the experienced furnacemen, that the pipe used has proved satisfactory. The pipe to the hall is a comparatively short one, and on account of the size of the halls and their height the air can flow out of this pipe very readily, and will naturally flow from it much easier than from pipes that lead into small rooms. Consequently a pipe of the same diameter will discharge into a hall which is open and three stories in height much more air than the same pipe would discharge into a room.

So far as the chapter hall is concerned, which is at the top of the building, it has a comparatively small wall and glass exposure, and is not so difficult to heat, as it is located over heated rooms. It is heated by means of a large vertical stack, in which a greater velocity will naturally be attained by the air, and, in consequence, a larger quantity of air will be discharged from the furnace through the pipe to this room than would be possible if the room was on the first floor.

In reference to the small bedroom and the bathroom, which seem to have pipes larger than is necessary, owing to the existing proportions shown, it is only necessary to say that when the hot air pipes are reduced too much in diameter the friction presented to the volume of air carried acts as a positive retarding force. This, and the fact that air traveling through small pipes naturally cools considerably before reaching the registers, reduces the efficiency. On this account it is necessary to have the pipes of ample size in order to have the air flow at all, so that the apparent discrepancy in the proportion of the pipes is due to sound common sense and reflects credit on the judgment of the designer of the heating system.

I always enjoy going over the various systems of heating which are presented in *The Metal Worker*, and while in some instances I would have arranged the work differently, I am free to add that I have derived benefit from examining them. It was after I had made a careful study of the system in the building which was heated by a Kelsey warm air generator that I thought it possible many readers had not noticed what had attracted my attention, and that they might be interested in the suggestions that came to my mind, if they were presented for their consideration.

Wrought Steel Registers.

The Hart & Cooley Company, New Britain, Conn., are manufacturing an attractive line of wrought steel registers, with solid wrought brass face plate and fitted with brass operating slide, and are about issuing a catalogue describing them. These registers are made from wrought metal only, no cast metal being used for any part. They are referred to as light in weight, with a consequent saving in freight, a uniform thickness of 1½ inches over all for all sizes affording a great saving in stock room. The operating slide is of extra heavy weight and strength to insure against breakage, and its construction is such, it is pointed out, as to insure a free and positive operation after years of use. The company state that their face plates will fit cast iron

borders of standard make; that holes in border frames for tin box loops are located same as in standard makes of cast iron; and that the net air openings of their registers will average the same as standard designs in cast iron. One design only is manufactured, the list of finishes being very complete. The company are at present making a line of sizes to cover all ordinary requirements, and will add other sizes as rapidly as possible. Their japanned registers are wrapped in paper. All other finishes are packed each register in a separate strawboard box, making a neat and durable package, protecting and preserving the finish. They make no charge for packing or cartage on shipments from factory, and assume all responsibility for breakage in transit up to point of delivery.

STOVES SHOULD BE READILY REPAIRABLE.

BY STOVEITE.

It would certainly seem, after all the years stoves have been manufactured, that the manufacturers themselves should have learned by this time that an essential feature in making a stove is to have it so constructed as to allow of it being repaired with the least possible inconvenience to every one concerned. Why anything so important should be given so little thought and attention is a mystery, unless it is because manufacturers are never compelled to take out old castings and put in new ones with their own hands. In the event of their ever attempting to do so, they would learn more about their business in five minutes than they would be able to forget in a lifetime.

From the way many stoves are constructed one would naturally think a studied effort had been made to put them together in such a manner as to drive stark mad the mechanic who is so unfortunate as to be called on to do any repairs to them.

Taking the old grates out of a range and replacing them with new ones should be a comparatively simple task; but with the ordinary range it is like taking Vicksburg to accomplish it. Of course, it is necessary to use bolts to fasten the parts together, but it is not always necessary to put the bolts in the most inaccessible places, so that the nuts cannot be reached with a wrench, a chisel, nor any other tool, when it is necessary to remove them.

Such a heathenish custom as making a range that must have the water back taken out in order to put in a new grate or brick rest is entirely out of place in the present century. And yet it is being done. The wonder is, some genius doesn't bring out a stove so fearfully and wonderfully made as to necessitate taking down the smoke pipe each time fuel is put on. Riveting the oven doors on cook stoves and ranges is another relic of barbarism that the retail dealer ought not to stand for any longer.

Manufacturers spend with a lavish hand in trying to produce stoves which present a handsome appearance, or work particularly well, but very little effort is made to construct them so that they can be repaired at a reasonable expense of time and effort.

As a rule, the dealer sells the stoves he is expected to furnish repairs for; so he can to a great extent select the makes of those most easily repaired, and push their sale. If this rule was followed more generally manufacturers would soon learn to cater to the tastes of the man on whom the brunt of the repairing falls. No dealer should give an order for stoves until he knows something about how they are constructed, as well as how they look; for no customer of his will thank him for selling him a stove so difficult to repair that it hardly pays to have small parts replaced when they give out. Perhaps the manufacturers, or some of them, would be pleased to have retailers who are practical men make suggestions. In any event, the retailer should take steps to get relief from some quarter. "Jest cussin'," as in the past, won't help matters.

THE Estate of P. D. Beckwith, proprietors of the Round Oak Stove Works, Dowagiac, Mich., have started up their plant again in full and with a force of 500 men.

RULES AND TABLES FOR HEATING WORK.

The following communication from a prominent house in the heating trade comments on the absence of standard rules and tables for the guidance of furnace-men in their work as a disadvantage to that method of heating. Furnace work has been said to be all "experiment and experience," without any tabulated record of methods from which rules could be formulated or calculations made of sufficient simplicity to be of use to the men who do furnace work. In the past few years there has been more study along these lines than heretofore, and more interest has been taken in such tabulated information as has been presented and is available.

While our correspondent points out the absence of such records and rules, and the consequent cost to the trade, which is cause for regret, the inability to supply them, much as they are to be desired, has led to the furnishing of rules for other classes of heating work which have been found reliable in an extended use. This disposition to help others is commendable and should be rewarded by those who have the best interests of the trade at heart by making a return in the presentation of such records, rules or tables as they may have found useful. We assure those who have any data of this character that the necessary space for its publication in our columns will be gladly accorded. Our correspondent's communication is as follows:

We think that the use of tables similar to the one shown on page 42 of *The Metal Worker* of November 9 is a step toward proper furnace heating, and will do away largely with the rank failures that have occurred so frequently in the furnace heating in the past. We use a similar table in making boiler estimates, and give it, as follows:

To select hot water radiation for residence heating each room should contain as many square feet of direct radiation as the square feet of glass surface, 5 per cent. of outside wall surface and 1 per cent. of the cubic contents of such room. For unusually exposed rooms add 10 per cent; to bathrooms add 10 per cent; to living rooms add 10 per cent.

For second-floor rooms deduct 10 per cent. from above rule.

For steam heating select two-thirds of the radiation required by the above rule.

We have found the above table to be very accurate, and if it contains any error it is in the way of providing more than enough of radiation. Probably this error sometimes prevents the securing of contracts that are given to dealers who provide less radiation, but we have found it absolutely safe and have never yet had a failure to heat with this rule used. We also use a base rule for estimating radiation for greenhouse work, which we give, as follows:

To get steam radiation for greenhouses: Three-tenths square foot of steam radiation will heat 100 square feet of glass 1 degree. To get radiation required, multiply each 100 square feet of glass surface by 0.3, and by the difference between the temperature required inside and the given temperature outside.

To get hot water radiation for greenhouses: Five-tenths square foot of hot water radiation will heat 100 square feet of glass 1 degree. To get radiation required, multiply each 100 square feet of glass surface by 0.5, and by the difference between the temperature required inside and the given temperature outside.

We have found these tables also very accurate, securing the best results. We think the trade lacks simple rules somewhat like the above that will enable estimating to be rapidly and accurately done. There seems to be more information on this subject in regard to boiler work than furnace work, and there is a modest fortune and a large share of fame awaiting the person who will write a book on furnace heating, giving in simple terms necessary information that can be understood both by the learned and the unlearned.

THE THOMAS, ROBERTS, STEVENSON COMPANY, Philadelphia, Pa., inform us that they are about erecting a three-story and basement warehouse, 55 x 158 feet, to give them increased office and storage facilities. In addition to the extensive line of Fortune coal heating and cooking apparatus, the company also make a fine variety of Fortune Gas Stoves and Ranges. Circulars advertising the Fortune Gas Heater and Ventilator, now being distributed among the trade, show one of the latest productions of the company.

Statistics on Stove Production.

In the item which was presented in *The Metal Worker* of last week the Weir Stove Company, Taunton, Mass., have departed somewhat from the secrecy which is customary in the stove trade as to the production of the various foundries. It is improbable that stove manufacturers generally are prepared to make a report on the number of stoves which they manufacture each year, and it is doubtful if any substantial benefit would attend a collection of such statistics. It is a matter of interest, however, to many stove dealers to know something about the stock which is carried by the houses from which they buy when the season is over. The statement is made that the Weir Stove Company had 6300 stoves on hand when the fall trade began. This would provide a stock of something over 20 stoves apiece for 300 customers. The further statement is made that the company have been making 75 stoves and 16 ranges a day in addition to further heating apparatus since that time. Assuming that September 1 was the beginning of stove buying, and that the foundry was running full to the end of November, this would give 90 days at practically 100 stoves a day, making 9000 more stoves available for distribution among those who had already laid in a stock and the late buyers. If the customers of the Weir Stove Company had properly protected their interests by having in stock, available for use, such a quantity of stoves as would be advisable for a good business man to carry, the producing capacity would show that the company were amply capable of replenishing the stock as it was disposed of.

New Monarch Goods for 1902.

The Monarch Stove & Mfg. Company, Mansfield, Ohio, makers of the Monarch line of vapor, oil and gas stoves and ovens, are at work upon their new line of patterns for the coming year, and will make some very attractive additions to the Monarch line of gasoline stoves, particularly in the Monarch New Method or the evaporating style of construction, and also in their complete line of high and low juniors. These patterns are virtually completed and photographs have been taken for the equipment of their salesmen. The Monarch wickless blue flame oil stoves will be quite radically improved over the patterns of last year. In fact, changes will be such as to quite give the company the right to say that Monarch wickless blue flame oil stoves for 1902 will be "right up with the drum major." They will also have a complete line of student lamp tank styles of construction, and in addition to this some other original features that will make these goods very attractive and desirable stock. Monarch asbestos lined ovens will be still further improved and the company are preparing for a very vigorous campaign in this department.

The Cahoun Soft Coal Stove.

The wide distribution and abundance of soft coal has been the incentive for many men to give time and study to the invention of soft coal stoves and other heat producing apparatus. Many constructions have been presented as a solution of what has proved a very difficult problem, but from their crudeness and similarity to laboratory apparatus, the great quantities of soft coal that are utilized are burned in stoves and apparatus not specially adapted to the purpose. The principal objections to the stoves used are that satisfactory combustion is not attained, and a regular fire cannot be maintained. Consequently an objectionable dense smoke is produced and the fire is low when most needed, having burned with uncontrollable and unnecessary fierceness at other times to the destruction of the vital parts of the fire chamber. This experience points to the need of specially constructed stoves and fire boxes for the use of this almost everywhere to be had fuel.

Of the many inventors who have attempted to supply this demand the method of bringing his invention to the notice of stove manufacturers adopted by E. R. Cahoun of Troy, N. Y., has much to commend it. After

having reached a point in his experiments which he thought warranted the production of his stove as an article of commerce, Mr. Cahoun had one of the fashionable stove pattern makers embody the principles of his invention in a cooking range of approved modern type and handsome design and appearance, so that an apparently completed article has been brought to the attention of stove manufacturers and the general public. Mr. Cahoun now has on exhibition at Troy, N. Y., several of his stoves in full operation, and invites inspection of them by anybody who may be interested.

ODD PLATES.

CHARLES W. BABCOCK still continues to be one of the popular salesmen of the Stove trade of New York City, to which he first came in the employ of George Starrett in 1870. He had previously been in the employ of Mr. Starrett at Richmond, Va. Mr. Babcock has an extensive acquaintance in the Stove trade, and also a wide knowledge of the Stoves, Ranges and Furnaces that have been on the market during his long experience, so that he is frequently consulted on repairs. For some time back he has made his headquarters with J. M. Litchfield, manager of the Mount Penn Stove Works' branch, at Beekman and Pearl streets, New York. In addition to his acquaintance with the Stove trade Mr. Babcock also has an extensive patronage among retail buyers, built up through his reputation for absolutely fair dealing. In showing goods he has no hesitation in naming the price, and in criticising many cheap goods as worthless he advises his customers to secure Stoves that have the merits of economy and efficiency, which make them satisfactory to purchasers.

THE PORTSMOUTH STOVE & RANGE COMPANY, Portsmouth, Ohio, are sending to the trade a leaflet devoted to their Mogul Furnace, which is presented as a heavy, substantial Furnace adapted for use in heating shops, large rooms, railroad stations and similar places, as well as small houses. It is presented as a plain, heavy Furnace with few joints, capable of doing good work and having a durability that will be appreciated.

THE CALDWELL FURNACE COMPANY of Fort Payne, Ala., have secured the plant formerly operated by the Alabama Hardware Company, and will make alterations and improvements and install new machinery for the purpose of manufacturing Furnaces, Heaters, Iron Mantels, Grates, &c.

THE MELLOTT HEATING COMPANY, 419 Market street, Camden, N. J., have been incorporated with a capital stock of \$50,000 to manufacture Stoves and Furnaces. Ell Thomas, E. B. Call, A. G. Thomas and P. B. Shirey are the incorporators.

THE STANDARD STEEL RANGE & MFG. COMPANY, Cleveland, Ohio, have moved into their new building. The company were compelled to seek more space on account of the large increase in their business. The new facilities give them double capacity.

THE MICHIGAN STOVE COMPANY are distributing exceedingly artistic circulars lithographed in colors. One of these received this week bears beautiful illustrations depicting scenes in child play. The printed portion of the circular refers to the claims made by the company for the superiority of their entire line of Garland Stoves and Ranges.

WILLIAM CRIBBEN, SR., who for 20 years had been foreman of the foundry department of the Cribben & Sexton Company, Chicago, died in that city on November 21. Mr. Cribben was a brother of Henry Cribben and was one of the veterans in the Stove trade.

At a recent meeting of the stockholders of the Pennington Foundry & Heater Company, at Pennington, N. J., the following Board of Directors was elected: Frank Le Bar, M. B. Moore, J. S. Burd, O. B. Gray, J. R. Bergen, E. S. Wells and J. W. Schneider. The board immediately organized and elected Frank Le Bar, president; M. B. Moore, vice-president and general manager, and J. S. Burd, secretary and treasurer.

It is announced that Richard A. Culter has recently consummated an arrangement whereby he becomes

sole owner of the Culter & Proctor Stove Company of Peoria, Ill. Mr. Culter has always held the controlling interest in the concern, the minority stock being held by the estate of his late partner, David C. Proctor. Mr. Culter could not purchase the stock held by the heirs until they had attained their majority, and this occurred only a month or two ago. We understand that Mr. Culter expects to make extensive additions to the already large plant, and to push more vigorously than ever the development of the Stove business.

Work on the new buildings for the Southern Stove Works, Richmond, Va., is making rapid progress, and the management now expect to take possession by January 1. When completed this will be one of the important Stove plants of the country, and will employ in the neighborhood of 500 men. One of the features will be a sheet metal department for the manufacture of Gas and Oil Stoves. The new plant will be in charge of C. M. Fleming. It is located in what is known as the West End, and it is expected that its presence will cause a demand for a number of new dwelling houses in that section.

THE plant and other effects of the Enterprise Stove Company, formerly known as the Joseph Bell Stove Works, situated in West Side, Muncie, Ind., have passed into the hands of Edwin J. Hickson, at the sale recently made by the Muncie Trust Company as receiver. We understand that Mr. Hickson will convert the present plant into an extensive establishment for the manufacture of iron and brass furniture, especially iron bedsteads. An unfinished lot of 500 Stoves and Heaters included in the sale will be completed and sold as soon as possible. Until they are all disposed of the old Stove plant will be continued in operation.

THE COLUMBUS STOVE WORKS, Columbus, Ohio, are sending out a four-page folder calling attention of the trade to the merits of the Columbus Steel Plate Range, which is constructed of heavy hammered and planished steel, and is offered in 42 styles and sizes. It is of an attractive exterior, the treatment of the end of the reservoir being especially rich and effective. The oven door is balanced and lined with asbestos. The oven bottom is constructed of No. 12 gauge, and the sides and top of No. 14 gauge metal. The body consists of No. 16 gauge steel, with heavy asbestos mill board between. The Columbus Stove Works are a comparatively new enterprise in Columbus, the proprietor being J. W. Hastings, who is well known throughout Central Ohio. He has had a long practical experience in the business, and the goods which he turns out are of a high order of merit.

THE SIMPSON STOVE & MFG. COMPANY of Pittsburgh, Pa., are distributing a very attractive and timely circular among the buyers of Gas Stoves, devoted to Simpson's Multiple Action Stove, which, in addition to being a strong radiator, also circulates the air. This Stove has a burner in two sections, so that the heating powers can be controlled. The circular also shows the Simpson Reflector Stove, an open gas fire, and the Duquesne Round Gas Heaters.

THE MCCLARY COMPANY of London, Ont., state that although their foundries are among the largest in Canada, they have been running full capacity all the year, as well as more or less overtime, and have enjoyed a volume of business which exceeded that of any corresponding period in their history. They have made a special feature of their Family Active Range, their Cornwall Steel Range and their Sunshine Furnace.

THE trade may have been somewhat surprised to see, in the advertisement of the American Furnace Company of St. Louis, Mo., printed in our last issue, a cut giving a sectional view of a furnace manufactured by another concern. We regret that this error occurred and call attention to the company's advertisement in the present issue, which presents the proper illustration that should have appeared last week.

United States Consul General Goodnow of Shanghai, China, reports the discontinuance of the exposition of American manufactures maintained in that city by the National Association of Manufacturers.

Window Ventilator.

The recent cold spell has caused many to tightly close their house and office windows to escape the chilling blasts that enter through the crevices, and, in consequence, many suffer from the lack of fresh air. To provide for the admission of the necessary fresh air, the Protective Ventilator Company, 129 Fulton street, New York, have made an air filtering device which can be used in connection with a window. These ventilators are said to be constructed on a scientific principle, and by their means a frequent change of air can be effected in an apartment without the risk and discomfort attending the opening of windows and the draft caused thereby. The ventilators are made of wood, and arranged so that the amount of air entering can be regulated and thrown toward the ceiling and diffused through the room. The company issue a four-page circular describing their device, and give a list of those who have used it with satisfactory effect.

Challenge Refrigerator Company.

The Challenge Refrigerator Company, Grand Haven, Mich., have issued two catalogues, one describing the Challenge Iceberg line and the other the Grand line. The first named catalogue comprises 56 pages, contains illustrations showing the rapid growth of the company's plant, gives a full description of the construction of the refrigerators and presents numerous illustrations of the styles manufactured under this name, the line comprising a great variety of sizes for domestic purposes and larger sizes for the use of grocers, restaurants, &c. The illustrations also show a number of most attractive constructions finished with sideboard features. The catalogue covering the Grand refrigerators comprises 24 pages, and also shows a complete line of sizes adapted to domestic requirements as well as larger sizes for grocers. This is a cheaper line, but the refrigerators are nevertheless manufactured with hard wood cases, and care has been taken with the insulating and the system of circulation to secure economical results in the consumption of ice.

The Defiance Cold Blast Lantern.

The Defiance Lantern & Stamping Company, Rochester, N. Y., are offering the lantern shown herewith. In Fig. 1 it is represented with the bail holding up the

Fig. 1.—Defiance Cold Blast Lantern.

globe for lighting. The arrangement of the hinge and the fluted globe plate are shown in Fig. 2. The globe may be turned back to trim the wick, or the globe removed for cleaning. Thus the patent combination lift

and hinge globe exposes the burner in two ways for lighting. The fluted globe plate, shown by the smaller cut in Fig. 2, is referred to as being so constructed as to throw the cold air directly against the globe, keeping the latter cool and less liable to be broken, and preventing the flame flickering. The lantern, it is remarked, gives

Fig. 2.—Hinged Feature and Fluted Globe Plate.

a bright, steady light, and is guaranteed by the company to be absolutely wind proof. They also make Nos. 0 and 2 Rochester lanterns, also in dash patterns.

Michigan Barrel Company's Refrigerators.

The Michigan Barrel Company, Grand Rapids, Mich., have just published a catalogue of Yukon, Economic and Chilkoot refrigerators. This catalogue comprises 74 pages, and thoroughly describes the system of insulation and circulation adopted for the different types of refrigerators manufactured. The eight walls of these refrigerators are 3 inches in thickness, and consist first of the zinc lining, next of a wood inner casing, then charcoal sheathing, next granite rock wool, then manila paper, next an air space, then more sheathing and finally the outside wooden case. The special points of the fixtures, hardware and shelves are the subject of detailed illustrations. The Yukon line is the leading line manufactured by the company. They comprise a great variety of sizes for domestic purposes, as well as for restaurants, grocers and others requiring larger space. The Economic line has as its special feature a white enamel provision chamber. This enamel is baked on galvanized iron, and is not paint, but a pure enamel. The special point covered by the use of this finish is the ease with which it can be cleaned. The enamel finish is also applied to some sizes of the Yukon line. The Chilkoot has been brought out to meet the demand for a moderate priced refrigerator.

Automatic Wringer Company.

The Automatic Wringer Company are operating a large factory at Muskegon Heights, Mich., in the manufacture of wringers, combination tub and wringer benches and washing machines. The line of wringers comprises the Automatic No. 10 and the Success. The Automatic wringer has an automatic adjustment which equalizes the roll pressure. A chain gear which connects the rolls avoids, it is stated, all side friction, and gives perfect freedom to the movement of the rolls. The machine, it is claimed, cannot be made to run out of gear. This machine is equipped with the new patented revolv-

ing clothes spreader, which compels the full use of the rolls, distributes the clothes evenly and feeds the fabric without friction. The rolls used are made of solid rubber, vulcanized on a cold rolled steel shaft. The Success wringer is also chain geared, and embodies many of the useful and important features of the Automatic machine, but is manufactured to be sold at a lower price. The combination tub and wringer bench is manufactured of hard maple, finished with malleable iron fittings. It is so arranged that the operator is never obliged to wring clothes left handed, the wringer being entirely separate, so that it can be reversed and always turned at the right hand side. The washing machine is named the Surf Washer, and is of the oscillating type. M. P. Janisch is president of the company and F. E. Jones secretary.

Ladders.

The Hercules Specialty Company, Erie, Pa., are sending to the trade a 32-page pamphlet devoted to the Hercules sectional ladders, scaffolding, step ladders and swinging stages. The catalogue shows, by means of half-tone engravings, the various styles of ladders and the safety connection used for fastening the different sections together, as well as the uses to which they can be put. One of the illustrations shows the sectional ladders extending to a height of 50 feet for painting the columns of a court house, another the ladders used for painting the steeple of a church, 45 feet above the roof, while other photographic reproductions display the ladders used for painting buildings, papering stairways, putting in valleys and gutters on roofs, putting on slate roofing, and for general building work. Extension planks, adjustable scaffold jacks, folding scaffold horses and step ladders are also presented in the catalogue, one page of which is devoted to the Hercules lawn swings, and another to the Hercules adjustable ironing board.

Stove and Hardware Dealers.

J. E. McNUTT, Confluence, Pa., advises us that he is desirous of selling out his retail Stove, Hardware, Tinware and House Furnishing Goods business in that town, with the intention of retiring from active work. Mr. McNutt says that the town of Confluence is favorably located on a line of railway, and that there is no similar store within 25 miles of him in any direction.

A STOCK COMPANY are organizing at Belfast, N. Y., to erect a factory for the manufacture of Tinware.

A LETTER from Bailey & Wilber, Vermilion, Ohio, dealers in General Hardware, Stoves and Tinware, and contractors for Plumbing and Sheet Metal work, informs us that their store and stock were consumed by fire on the night of December 3. They state that their loss amounted to \$5000, which is covered by an insurance of \$4500. The firm are temporarily located in the Wells Block, where they are continuing their regular business until they can secure more suitable quarters. They desire catalogues and quotations on goods in their line.

THE WINDSOR MFG. CORPORATION, Windsor, Conn., have been incorporated with a capital stock of \$10,000, of which \$5000 has been paid in. The new concern will manufacture a patent Meat Chopper and other specialties. The officers are Thomas B. Chapman, president; William S. Post, vice-president, and Robert H. Chapman, secretary.

THE LALANCE & GROSJEAN MFG. COMPANY of New York City are distributing a leaflet showing a reduced fac-simile of the label used on all their Agate Nickel Steel Ware. On the back of the circular are printed testimonials from cooking authorities on the excellence of this ware. The Agate Nickel Steel Ware is made of a steel body, nickel plated and covered with a good double coat of absolutely pure Agate enamel, thus rendering the ware absolutely safe and durable.

We have received from the Star Enameling & Stamping Company, Pittsburgh, Pa., a batch of circulars illustrating and describing some of their specialties, including the Star and Oval Dinner Pails, Pittsburgh Tin and Gal-

vanized Oil Cans and Wash Boilers, of which the company make a large variety.

GEO. A. STEELE has sold his Hardware, Stove and Agricultural Implement business in Frankfort, Mo., to R. S. Shotwell. Mr. Shotwell will move into a new store room, now under construction, about the middle of December. At present he is handling general Hardware, Stoves and Sporting Goods, but in the spring contemplates taking up Farming Implements and Vehicles in addition.

J. B. S. CASE has lately embarked in the Hardware line at Anadarko, Oklahoma. Besides Shelf and Heavy Hardware, Mr. Case is handling Stoves and Tinware and Sporting Goods.

J. A. McCOPPIN & Co. is the style of a firm who have lately opened up in business at Hillsboro, Ohio, as dealers in Hardware, Stoves, Iron and Steel, &c. The new house would be pleased to receive catalogues, price-lists, &c., relating to Hardware and allied supplies.

BEEVER BROS., Hardware merchants, Jellico, Tenn., have opened a branch store at La Follette, which will be conducted under the style of La Follette Hardware Company. The line carried embraces general Hardware, Stoves, Tinware, Sash, Doors, &c.

DUNN & WINNING have bought the Hardware, Stove, Farm Implement, Harness and Vehicle business of Starr & Sutton, Milo, Iowa. They have rearranged the store and made a number of improvements.

PACKARD HARDWARE COMPANY, New Bedford, Mass., have opened a branch store at Fairhaven, where they are carrying a stock comprising Shelf Hardware, Tinware, Farming Implements, Wooden Ware, &c.

MINERS' HARDWARE COMPANY, Joplin, Mo., have incorporated, with a capital of \$10,000, to carry on the wholesale and retail business in Shelf and Heavy Hardware, Stoves, Tinware, Agricultural Implements, Sporting Goods, Miners' Supplies, &c. They have just moved into a large double store, 50 x 100 feet.

J. T. McDONALD & Co. are successors to Fields & Evans, Creston, Iowa, dealers in Shelf and Heavy Hardware, Stoves and Tinware, Sporting Goods, &c.

COSMOPOLITAN INCANDESCENT GAS LIGHT COMPANY, 176 Madison street, Chicago, have gotten out an illustrated net price-list of a few of their staples, such as Mantles, Burners, Chimneys, Clusters, Outdoor Globes and Lamps, fancy hanging Lamp, Mica Canopies, Portables, &c. If interested in fancy Portables, fancy or colored Glassware and miscellaneous goods, they request the trade to send for their catalogue No. 4.

THE old buildings of the St. Louis Stamping Company at Cass avenue and Second and Third streets, St. Louis, Mo., are about to be thoroughly overhauled and refitted with new machinery for the manufacture of Tinware as soon as the reconstruction work is completed. The National Enameling & Stamping Company are spending about \$25,000 on the necessary improvements.

OFFICIAL ANNOUNCEMENT has been made that the annual meeting of the Minnesota Retail Hardware Dealers' Association will be held in St. Paul on February 26, 27 and 28 next.

J. W. WOLVERTON, formerly a member of the firm of Wolverton & Bird, Rich Hill, Mo., has opened a new store in Lawton, Oklahoma, handling Shelf and Heavy Hardware, Stoves, Tinware, Sporting Goods, Plumbing Supplies, &c.

T. J. O'NEIL has succeeded Martin O'Neill & Co. in the Hardware, Stove and Farming Implement business in Osage City, Kan.

GRIFFIN MFG. COMPANY, Erie, Pa., issue a price-list of Griffin's Pressed Steel Shelf Brackets, Folding Brackets, Lavatory and Flush Tank Brackets, Drawer Pulls, Door Bolts, &c. An illustration is given of their large new plant.

FRED. MACK AND ARTHUR BISHOP have formed a partnership in the Hardware, Tinware and Furniture business in Erie, Kan., under the style of Bishop Hardware & Furniture Company.

Two-Piece Sheet Metal Practice Boat.

BY MARTIN L. KAISER.

The desire manifested by readers of *The Metal Worker* to build boats of sheet metal I have satisfied for myself in making the boat shown in Fig. 1, and as it was not a very difficult job, others can readily follow or modify my plan. To aid them I give the following description of the methods I used for making a small boat of metal,

96 inches long, should be marked and turned up in the cornice brake, as shown in Fig. 2. This forms the keel and at the same time provides the requisite stiffness for the bottom. Both sheets should now be formed up in the brake or over a large size pipe, to present the appearance of a trough, as shown in Fig. 3. In one end of each trough should be nailed a temporary wood brace about 1 x 4 inches, and of a length corresponding to the beam of the boat, which in this case is 19 inches.

At the end opposite the brace the curve of the trough should be straightened out, and the two sides brought together to form the prows. Each piece will then look

Two Piece Sheet Metal Practice Boat.—Fig. 1.—General View of Boat.

without the use of patterns, and with no special machinery or models. I hope the information will be interesting to those who would like a light, fast boat—a little cranky, it is true—easily and cheaply made and adapted to either paddle or oars. This boat has proved perfectly safe in use during the past three seasons, and no defect in construction has yet appeared. I wish to state, however, that when I build the next boat of this kind it will be about the same width or beam, but 20 feet long instead of 16. The outrigger oar locks will also

like one-half of the boat, but with an exaggerated sheer, and will present the appearance shown by Fig. 4. In this operation care should be taken that the work be done a little at a time on each side, so that the keel may not be unduly strained, as it is very important that it

Fig. 4.—Forming the Prow.

Fig. 2.—The First Bend in the Hull Strips.

project further from the boat, and the spoon oars will be 9 feet long instead of 7 feet.

One of the important requisites in the use of a boat of this kind is the ability to swim, though I have thus far had no occasion to exercise this accomplishment in using this or another sheet metal boat of somewhat wider beam and different construction. The boat, of course, is not intended for use in a gale. Nevertheless

Fig. 3.—Forming the Hull.

there are other things less exhilarating than a race across the waves and an arrival at the landing with about 6 gallons of water thrown in by the wave crests.

The present description will have nothing to do with pattern cutting, but will be the method followed in evolving the first boat of the kind. To begin with, two sheets of No. 27 galvanized iron or steel, 30 inches wide and

should remain perfectly straight. At the end of the prow the V-shaped keel should also be drawn together, and both it and the curved sides gradually tapered out to the required size at the middle. The two ends of the prows may now be temporarily fastened together by means of $\frac{1}{2}$ x 3-16 inch stove bolts, and the corner at the bottom cut on a curve, as shown by dotted lines in Fig. 4.

Having determined the amount of sheer desired in the finished boat, the surplus metal should be cut away on a line marked for it. It should be remembered that the amount of sheer may be governed somewhat by the bevel of the sides of the boat at the top of the middle section.

Fig. 5.—The Prow Piece.

If the sides are perpendicular at the point marked A in Fig. 4 there would be no sheer in the finished boat, while the more the sides at that point are inclined outward the more sheer will be produced. In the present boat the sheer is only 2 inches—that is, the depth at the prow is but 2 inches more than the depth at the middle section. The sides of the boat may, therefore, be practically perpendicular.

The metal at the prow should now have all the buckles hammered out, which may be done by using a smooth faced hammer on the inside and holding the square head

on the outside, thereby stretching the metal. The prow ends may then be riveted together permanently. A piece of sheet iron should be cut the shape of the prow, as shown in Fig. 5, about $1\frac{1}{4}$ inches wide, and so placed that the outer edge should project about $\frac{1}{4}$ inch beyond the metal of the sides at the prow. Removing the temporary stove bolts, this piece should be riveted, together with the two thicknesses of metal at the prow, with rivets $\frac{3}{4}$ inch apart, and the projecting edge of the separate piece clinched over the raw edges of the prow. The seam should then be thoroughly sweated with solder. The air chambers should extend about 28 inches back from the points of the prows, and should be air tight.

Fig. 6.—The Top of the Air Chamber.

They are to prevent sinking should the boat fill with water. A piece cut the required size with 1-inch flanges, and extended as shown at C in Fig. 6, should be bent down at the dotted line A B. This forms the top and one end of the air chamber, and should be riveted to the sides of the boat, so that the top of the air chamber will be $1\frac{1}{2}$ inches below the top of the boat. The extension C, Fig. 6, should be long enough so that it fits snugly in place, inclined at an angle, and should be carefully soldered to the sides of the boat, instead of being riveted. When this is done, the two parts of the boat (which should be alike) may be fitted together at the middle.

Two boards with straight edges 1 inch apart should be nailed to a level floor. The keel may be set down in the groove thus formed and a level used on the wood braces. A few blocks nailed to the floor and marked at the height of the sides will enable the boat to be removed from these primitive stocks and replaced exactly as be-

screws. The outer strip is $\frac{3}{4} \times 1\frac{1}{2}$ inches and is made thicker in order to more securely hold the tails of the screws, as shown at A in Fig. 8. The wood at the extreme end of the prows should be rounded at the points and bound with sheet copper fastened with small brass

Fig. 9.—Plan and Side Elevation of Seat and Outriggers.

nails. To this copper may be soldered a small tube, in which may be inserted the staff of a small flag.

The boat, or canoe, at this point weighs 35 pounds, and with a double bladed paddle forms a very satisfactory fast canoe for use in comparatively quiet waters. It may be painted to suit the individual taste. To transform it into a practice boat the seat and oars may be

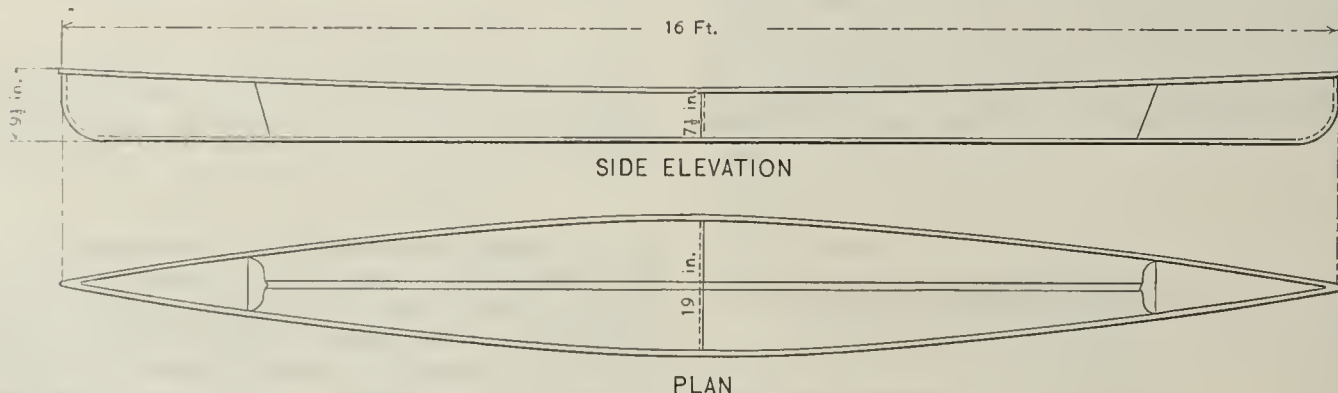

Fig. 7.—Plan and Side Elevation of Two Parts Connected.

fore, without frequent recourse to the level and square. The two ends should be accurately fitted together with a lap of 1 inch and lightly tacked together with solder. The boat should then be turned over and a chalk line stretched along the keel. Any inaccuracies should be corrected, and the middle connecting seam securely riveted with rivets $\frac{3}{4}$ inch apart and soaked with solder

Fig. 3.—Cross Section, Showing Gunwale Strip, Bottom Board and Oarlock Outriggers.

inside and outside. The boat will then present the appearance shown in Fig. 7, which gives both the plan and side elevation with dimensions.

The topsides, or gunwale, is composed of two strips of white pine with the sheet iron between, and screwed together, with screws about 4 inches apart. The inner strip, which is $\frac{3}{8} \times 1\frac{1}{2}$ inches, receives the heads of the

added. These are entirely separate from the shell. A white pine bottom board 1 foot wide, 4 feet long and $1\frac{1}{4}$ inches thick is shaved to fit the bottom of the shell near the middle section.

A pair of irons should be prepared by the blacksmith to fit loosely inside the shell at that point, and extend out over the sides 12 inches, joining together at the ends to receive the swivel oar locks, as shown in Figs. 8 and 9. These irons are $\frac{5}{8}$ inch round where they overhang the water and are flattened on the inside of the boat. The under side of the bottom board is gouged out, so that the irons set in the wood, and the irons are securely bolted to the board, taking care that the bolts are countersunk, so that they do not scratch the shell of the boat. A foot rest with braces and toe straps should be securely screwed to one end of the board, and guiding strips for the seat rollers fastened in about the position shown in Fig. 8. Inside the guide places, where the wheels are to run, two strips of hard wood are inlaid to take the wear.

The roller seat should be gouged out of a piece of white pine about 7 inches square, and provided with rollers, which may be procured at any hardware store. It should be borne in mind that the lower the seat and

rollers are placed the steadier the boat will be. With such a removable seat the position in the boat may be varied to suit, and as both ends of the boat are alike, the bottom board and seat may be reversed without necessitating the turning of the boat. Feathering spoon oars should preferably be used, although it takes a little practice to become accustomed to the proper turning of the wrist.

The cost of the material for the shell alone, including paint, should not be more than \$2.50. The time and trouble will be more than repaid by the pleasure of one season's use. The keel, as shown, would be insufficient for an ordinary boat, but for such a boat it is ample, because the boat, when loaded, acts as a keel for itself. It may be added that on one occasion a man weighing 150 pounds shipped so much water into the boat that it sank to a point where the water was half way between hips and shoulders, and the boat was then rowed ashore in the usual way, except that the boat itself was entirely under water.

Danzer's Lightning Edger.

We present herewith an illustration of Danzer's Lightning edger, manufactured by the Danzer Metal Works, Hagerstown, Md., and which has been patented by that concern. These machines are made for hand, foot and belt power. The edger is described as being so simple in operation that a boy can work it, while it does remarkably rapid work. The manufacturers claim that

Danzer's Lightning Edger.—Fig. 1.—View of Hand Tool.

by its use a box of 20 x 28 tin can be edged in ten minutes. It will also edge No. 27 pipe iron equally as well as tin. The edger will hook all four edges of a sheet for flat seam roofing put down with cleats, or it will hook two edges and square up the other two for

Fig. 2.—Edger for Foot Power.

flat seam roofing nailed down. The sheet of tin is edged by a short forward movement of the handle, the sheet being kicked out without moving it or turning it over the top of the machine. The tool is made to edge from 3-16 to 5/8 inch wide. It is made in two sizes, one known

as No. 20 being 21 inches wide and weighing 70 pounds when crated and the other, No. 30, being 31 inches wide and weighing 95 pounds. The foot power machine is built on a hard wood table strongly braced and bolted. This tool, it is claimed, has edged a box of 20 x 28 tin in six and three-quarter minutes by actual test. The edgers are made with solid cast iron bed and the finest steel blades.

THE NEW SHEET MILL OF LAUGHLIN NAIL COMPANY.

The Laughlin Nail Company of Wheeling, W. Va., have recently finished and put in operation a very com-

plete sheet mill plant, located at Martin's Ferry, Ohio. Active work on the erection of the plant was started last January. The mill is located just south of the large cut nail mill and shovel works of the Laughlin Nail Company, and at right angles to the tracks of the Cleveland & Pittsburgh Railroad. There is one main building, which contains the hot mills, and which is 60 feet in the clear and 286 feet long. On one side it has a lean-to 30 x 242 feet and another 30 x 286 feet. There are also three producer houses, each 44 x 27 feet, and boiler house 35 x 66 feet. The main building is of steel construction and is commanded by a 20-ton three-motor electric traveling crane, built by Pawling & Harnischfeger of Milwaukee, Wis. The equipment consists of two stands of roughing rolls, 26 x 44 inches, and four stands of hot mills, two of which are 26 x 44 inches and the other two 26 x 38 inches. There are also two stands of cold mills, 26 x 44 inches.

These mills are driven by two 32 x 72 inch Corliss engines, direct connected to rolls, and built by C. & G. Cooper Company of Mount Vernon, Ohio. Steam is furnished by two batteries of Sterling boilers, consisting of two boilers to the battery, of 258 horse-power each, giving a total steam capacity of 1032 horse-power. Steam is taken from these boilers through 6-inch expansion U bends to a 16-inch header. From there the steam is taken down through a 12-inch main steam line through a tunnel and to the engine through a 36-inch Austin receiver separator. It enters the engine under the floor, giving a clear floor space around the engines, there being no overhead pipes to interfere with the operation of the crane. The boilers are hand fired, coal be-

ing delivered by gravity railway from mines owned by the company. The ashes drop through the floor to an underground car and are taken to the river bank.

The electric plant consists of two 90 horse-power Harrisburg standard engines, direct connected to two Westinghouse generators. Switchboard consists of one Westinghouse black enameled board, containing two generator panels and two feeder panels. The machines are arranged to operate in multiple, in case any excess load is required over one machine.

The company receive slabs weighing from 350 to 550 pounds, 7½ inches wide, which are reheated in their own large plate mill, being given five passes in the roughing mill and one pass in the finishing mill. After being sheared by an automatic driven shear the bars are loaded into trucks and taken to the heating furnaces in the sheet mill. The bars are picked up by crane, taken to pair furnaces and are then handled by the mill crew; after being heated they are then taken to roughing mill for two passes, then to finishing mills, where they are finished. After being sheared the packs are opened and then taken to the cold rolls and cold rolled. The sheets are then picked up by a crane and taken to the annealing floor, where the pack is charged on annealed bottoms, annealed, and, after doing this, again picked up by the crane and placed on tracks, then delivered to the galvanizing, corrugating and metal ceiling departments. In case the black sheets are to be sold in the open market they are delivered direct to the car, a track having been placed in the mill for this purpose.

Particular attention is paid by the Laughlin Nail Company to the annealing of their sheets, as the firm believe that only by proper annealing can the best quality of sheets be obtained. The annealing furnaces were built by William Swindell & Brothers of Pittsburgh and are fired by producer gas. The furnaces are charged by a special device invented by H. A. Strauss, engineer, of Wheeling, who designed and built the sheet plant complete. The sheet and pair furnaces, six double Swindell patent water seal gas producers, 10 feet in diameter, were built by William Swindell & Brothers, the well-known engineers and contractors, of Pittsburgh.

While it is possible the Laughlin Nail Company will market black sheets occasionally, it is the intention of the firm to market practically their entire product in galvanized, corrugated and crimped sheets, corrugated roofing, pressed standing seam and rolled roofing, weather board and brick siding conductor pipe, eave trough and steel ceilings. The firm have installed complete equipment, consisting of the latest machinery, and have also built galvanizing pots on entirely new lines. Two warehouses have been provided for the accommodation of the black sheets, one adjoining the pickling room, for galvanizing, the other adjoining the paint mills.

Special attention has been given to the artistic appearance of the steel ceilings which the concern are making. A distinct departure has been made by the firm in the decorative quality of their steel ceilings. The concern have adopted a lapping joint, which is entirely new and which conceals the sheared edges of the plates, requiring no swedging and only sufficient nailing to hold the pieces up. The concern are already in receipt of quite a number of orders for their new designs for steel ceilings, which they are now executing.

The entire plant has ample shipping facilities, having direct connection with the Baltimore & Ohio, Wheeling & Lake Erie, Cleveland, Lorain & Wheeling, the Wheeling Terminal and the Cleveland & Pittsburgh roads. The company control river frontage, giving the advantage of river shipments. Taken as a whole this new sheet plant, with galvanizing, roofing and ceiling departments, is of modern equipment throughout and is certain to produce a maximum output of product. The first sheets were rolled in the new mill in October and the plant has been in successful operation right along since that time. While only four hot mills have been installed, provision has been made in every way for two additional mills, which will be built within a short time. The output of black sheets will be from 40 to 50 tons a day, practically all of which will be used in the roofing, ceiling and siding departments.

The officers of the Laughlin Nail Company are W. L. Glesner, president, and F. K. Dixon, secretary. The roofing and ceiling departments are under the direct supervision of J. K. Davies, the sheet mill by John Usher, and the galvanizing and corrugating departments by W. Bates Woods, who also designed and built the corrugating and galvanizing works.

What Should a Cornice Maker Know?

A question of interest to cornice makers generally is raised by a Philadelphia contributor, whose letter is as follows:

I receive *The Metal Worker* regularly, reading all parts, and in the Labor Exchange of a recent number I find the following advertisement from a metropolitan house:

Wanted—Three cornice and skylight makers; men who can take out and complete contracts from drawings. No tinsmith pretending to be a corniceman need apply.

In the locality of New York and Jersey City the advertiser will not find many men who can fill his wants. I was working in New York about three years ago and noticed an advertisement in the *Herald*, where such a man was wanted in a small city on the Hudson River. I telegraphed to the advertiser that I could fill his wants if the place was open. I received the answer during the afternoon, "Come up at once," and I went to see the man. He told me that he had had at least 15 men to come to him from New York. When he showed them a blue print and asked, "Can you make that cornice, bay window, pediment or skylight?" they all said, "Yes. Is it cut out and formed up?" Of course he said, "No. There is the print. I want what I advertised for." They all went back home. I learned that he had been advertising for five days. I took the job, and from the blue prints cut out and made up the work and finished it on the building.

Now, what I would like to know is, WHAT IS A CORNICE MAKER SUPPOSED TO KNOW? I ask this question because I have seen and handled some of the most ignorant men answering advertisements for cornice makers here in Philadelphia that I have ever struck. I have worked in and have had charge of some good sized shops, but became so disgusted with the charge of any part of a large shop that I am now working at the bench, and am able to get within 20 cents per day as much as the man who has charge of the shop.

This is a very interesting letter. Although it may seem to many rather severe, it is presented with a view to affording the trade an opportunity to discuss the question with a view to correcting such trouble as may exist, and aiding those who are in this field of labor to acquit themselves more creditably when called upon to work from blue prints. In this trade there are doubtless many men who are so qualified, and are considered invaluable by their employers. But these men have not reached that important position without making some methodical effort. *The Metal Worker* would be glad to have them give an account of the course they pursued in fitting themselves. It is a foregone conclusion that they have studied as well as worked with their hands. Doubtless they have read different books and have books for reference when especially difficult problems are presented. We shall be glad to have them give a list of the books they consider useful reading for the ambitious workman, whether a beginner or a hand who is desirous of becoming more proficient in his work. Some men could explain with advantage their method of reading blue prints and plans to different scales, the place where they begin to read, and their method of taking up the work in detail.

If the qualified members of the trade will be so generous toward their fellow workmen as to write such letters and explanations *The Metal Worker* would gladly present them. There can be no doubt it would make interesting reading and prove a great help in teaching what a cornice maker should know, and starting some careless men into taking a greater interest in their work, which would surely develop their skill and knowledge and add to their value. There is a demand for men who are something more than mere workmen, who have taken pains to acquire their education and become skillful and proficient.

Plans for Increased Sheet and Tin Plate Capacity.

The Pittsburgh *Chronicle-Telegraph* of December 12 says: "It has been decided by the American Sheet Steel Company to install additional mills for the rolling of heavier gauges, and the work is to be begun at a number of the plants in a short time. The American Tin Plate Company will also in the near future install machinery for the rolling of black plates for tin mills that will be largely automatic. It is said on reliable authority that machinery in this process will do from two-thirds to three-fourths of the work now done by hand on the hot mills, and the output will be greatly increased. With the new method it is estimated that the American Tin Plate Company will be able to compete with foreign manufacturers at home without the aid of tariff, which would result in the United States becoming the greatest tin plate manufacturing country in the world."

FLASHINGS.

T. J. COSTELLO, superintendent of the Tin Plate mills of the N. & G. Taylor Company at Cumberland, Md., has been appointed superintendent of the new plant of the Maryland Sheet Steel Company at that place. A large force is now at work transforming the mill.

THE JACKSON IRON & TIN PLATE COMPANY of Clarksburg, W. Va., are preparing to start their new works soon after the beginning of the year. All the machinery is now in position.

ONE of the principal recommendations of the Roof Cement manufactured by George Callahan & Co., 218 Front street, New York, is that it can be applied in a rain storm. The Cement is claimed to have the quality of sticking to a wet roof, as well as of always remaining elastic and never becoming hard in the packages, even if the cover is left off and the Cement exposed to the air. The fact that it can be used to stop leaks in roofs when water is running over the broken Tin recommends this Cement to the consideration of roofers and all interested in similar work.

CONTRACTS have been taken by the Bridgeport Boller & Pipe Covering Company, Bridgeport, Conn., for 3000 square feet of Gravel Roofing for the Lounsbery & Bissell Company in Winnipauk and for 2500 square feet for the Norwalk Mills Company at the same place.

THE SOUTHERN CAN COMPANY of Baltimore, Md., recently incorporated, with a capital stock of \$5000, by E. Edward Gibbs, Walter W. Crosby, Robert D. Schurder, Samuel H. T. Hayes and James F. Andrews, will manufacture Tin Cans and other articles of Sheet Metal.

THE LAUGHLIN SHEET MILL, at Wheeling, W. Va., has resumed after a temporary shut down.

M. J. HYLAND, Middletown, Conn., has contracts for roofing the Congregational Church in Groton, a masonic building in Greenport, L. I., the new factory of Wilcox, Crittenden & Co., the boiler house at the Hospital for the Insane, T. McDonough Russell's new residence and Schaefer's bakery in Middletown. The roofs will all be of Slate or Gravel.

THE deal for the Cumberland plant, sold recently by the Crucible Steel Company of America to Albert F.

Baumgartem of Pittsburgh, who in turn deeds it to the Maryland Sheet Steel Company for \$65,000, was put on record at Cumberland, Md., last week.

THREE of the ten mills in the Chester Works of the American Tin Plate Company, at Chester, W. Va., have been started up. The other seven mills will be put in operation shortly after the first of the year. This was formerly a Sheet plant owned by the Chester Rolling Mill Company, but was taken over by the American Sheet Steel Company. The Sheet rolls were afterward removed and tin rolls substituted, the plant now being owned by the American Tin Plate Company.

THE PARKERSBURG IRON & STEEL COMPANY of Pittsburgh, with works at Parkersburg, W. Va., are building a forge mill in addition to their six-mill Sheet plant, the approximate cost being about \$100,000. The Sheet mills of this concern are nearly ready for operation and will be started this month. The forge mill will consist of puddling furnaces, knobbling fires, Bar mill and Skelp mill, with necessary equipments.

THE CARNAHAN TIN PLATE & SHEET COMPANY of Canton, Ohio, placed two mills of their new plant in operation last Monday. The housings and spindles for three hot mills are in position, and the rolls have been placed in one of them. The new offices of the mill have been completed.

THE WHITAKER IRON COMPANY, Wheeling, W. Va., manufacturers of Black and Galvanized Sheet Iron, Tin and Terne Plate, are now operating four Tin mills and also four Sheet mills. They are adding three new Sheet mills, which they will have in operation in March or April next. The Whitaker Iron Company and the Wheeling Corrugating Company are allied interests and operate between them four Sheet mills, four Tin mills, eight Tinning sets and a galvanizing department. N. E. Whitaker is president of the Whitaker Iron Company, and A. C. Whitaker is secretary.

LOUIS C. KRUMMEL has resigned his position as chief engineer and general shop manager of the machinery department of the American Can Company, and has established himself as consulting mechanical engineer at Austin, Ill. He has been connected with the E. W. Bliss Company of Brooklyn, and the American Can Company in Chicago, as technical member of the firm operating the Rudolphi & Krummel Machine Works, Chicago, covering a continuous period of 15 years.

THE VULCAN SHEET METAL COMPANY, Denver, Col., recently organized, have leased a plant and will make Sheet Steel pipe and other Sheet Metal Work. The company are closely allied to the Vulcan Iron Works Company of that city.

IN railroad circles the report is current that W. B. Leeds, who has been prominently identified with the Tin Plate industry and Moore group of Iron consolidations, is to become president of the Rock Island Railroad.

THE CARNAHAN TIN PLATE & SHEET COMPANY, Canton, Ohio, manufacturers of Tin and Terne Plates and Sheet Steel, have made plans for the building of an open hearth Steel plant and will probably commence work on it in the near future.

WILLIAM REIFERSCHIED, a Cornice maker and Sheet Iron worker of Streator, Ill., has invented an airship and has been fortunate in securing the backing of a number of Chicago capitalists to make a practical demonstration of his invention. It is stated that the demonstration is to be made in the spring. The airship consists of a cigar-shaped Aluminum frame, 80 feet long, to contain the balloon, with mechanical appliances attached, which, it is asserted, will enable the ship to be dirigible.

THE annual meeting of the American Tin Plate Company is announced to be held in Jersey City, N. J., January 21, 1902.

THE VULCAN WESTERN COMPANY, Streator, Ill., are daily shipping large quantities of Tin Scrap to Ensley, Ala. The company purchase Tin Scrap, which they subject to a special chemical process by which they remove the Tin, after which the Scrap is baled and shipped to steel works for remelting purposes.

OPENING OF THE TWENTY-FIRST SEASON OF THE NEW YORK TRADE SCHOOL.

The formal opening of the day classes of the twenty-first season of the New York Trade School took place on Wednesday afternoon in the auditorium of the school, at Sixty-seventh street and First avenue, New York, the actual assembling of the classes having taken place on Monday. The hall was well filled by young men who are enrolled for instruction in the various trade classes for the 1901-1902 season. Superintendent H. V. Brill introduced President R. Fulton Cutting of the Board of Trustees, who extended a cordial greeting to the young men.

Mr. Cutting, in the course of an earnest and practical talk to the students, impressed upon them the fact that they were entering upon what would probably prove the most important four months of their lives, and that the time spent at the New York Trade School was a precious opportunity for each student to lay broad and deep foundations for a subsequent successful career in his chosen trade. The trade school, the speaker said, gives the opportunity to learn, but the results depend absolutely upon the pupils themselves. The school itself can do little or nothing for them unless they themselves take full advantage of all the opportunities offered by the school. In that way success will come. It is not alone the brainy men who make a success of life; all who go about it in the right way can achieve success, provided they have the fundamental requirements. There is no royal road to success; success never comes to a man—he has to earn it. Success has no motive power of its own; human energy alone supplies that; earnest, diligent, hard, patient work is needed; this is the secret of success. But a permanent success also requires another element—that of character. Honesty and straightforwardness must be behind the work. The aim of the New York Trade School, said Mr. Cutting, is not only to make good tradesmen, but also good Americans. That is what it stands for primarily. He closed by urging the men not to be afraid to do the best work that lies within their power, irrespective of any arguments that may be brought forward by certain trades unions, to the effect that a man should not do more than a certain amount of work a day. This is a profound economic error. Every tradesman should aim to do the most and best work he can.

Mr. Cutting then said that he would like the boys to hear from one or two men who had themselves obtained success in the trades in which they were about to embark, and introduced Edward Murphy, one of the committee of the school. Mr. Murphy, who is always a favorite with the Trade School boys, received a hearty ovation when he came forward to speak. In the course of his remarks he paid a fine tribute to the memory and work of the late Colonel Auchmuty, the founder of the school, whom he characterized as *par excellence* the friend of the American boy. After some practical and kindly words of advice and encouragement to the new pupils Mr. Murphy gave place to John Beattie, another veteran member of the school committee.

Mr. Beattie is a speaker who is always acceptable to the Trade School students and his remarks were listened to with close attention. Among other things Mr. Beattie said that the young men now before him were embarking upon the opportunity of their lives. In his early trade life it took him at least four years to acquire the theory of his trade, and then he did not get it nearly as well as the New York Trade School students were able to do in four months. He urged them to make up their minds to work hard and derive all the benefits possible from their present opportunities. Each student must in future be one of two things—either simply a cog in the wheel or the hand that directs the wheel. In coming to the New York Trade School young men were given the chance to qualify themselves for becoming directing powers rather than mere machines. The meeting was closed with a few words of welcome to the new students by Superintendent Brill.

The enrollment in the various classes this season has been fully up to the average. The day plumbing class

starts with 94 members, drawn from about 25 States; the electrical class has 50 members; carpentry, 24; brick-laying, 15; house and sign painting, 15, and the cornice class, 8 members. It was remarked that the young men who have entered the school this season appear to be of a higher type of intelligence than ever before, proving that the advantages offered by the institution are being more widely appreciated from year to year.

We print below a list of pupils in the day plumbing class:

DAY PLUMBING CLASS, 1901-1902.

Allen, Loren D., Hammond, N. Y.
 Berry, Dwight C., Roseburg, Ore.
 Borthwick, John A., Portland, Ore.
 Baumann, Charles V., Newark, N. J.
 Becker, George, Maquoketa, Iowa.
 Buchtenkirch, John, New York City.
 Coffey, James, Charleston, W. Va.
 Cook, William G., Bushkill, Pa.
 Cheever, John E., Manchester, Mass.
 Derrenbacher, M. F., Kingston, N. Y.
 Doran, Edward F., Greenville, N. J.
 Dour, Leon T., New York City.
 Doering, Frank L., Wapakoneta, Ohio.
 Dudley, Alfred A., Montclair, N. J.
 Delacom, George A., Derrick City, Pa.
 Dickinson, James W., Port Washington, L. I., N. Y.
 Evans, John T., Butte, Mont.
 Enright, Michael J., Raritan, N. J.
 Ford, Thomas J., Brooklyn, N. Y.
 Flinn, James, Youngstown, Ohio.
 Ford, Paul J., Brooklyn, N. Y.
 Ford, Francis, Brooklyn, N. Y.
 Fretz, Harry N., Cedar Grove, N. J.
 Fall, Martin, Logansport, Ind.
 Gay, Henry K., Nashua, N. H.
 Garrison, Ralph H., Vineland, N. J.
 Gunther, John M., Jr., Spring Valley, Ill.
 Gilson, Geoffrey G., Corry, Pa.
 Grant, William D., Kane, Pa.
 Griswold, Albert E., Holyoke, Mass.
 Gould, Clarence R., Friendship, N. Y.
 Gray, Clarence A., Allegheny, Pa.
 Howard, John G., Raleigh, N. C.
 Hansen, Andrew, Algona, Iowa.
 Henry, Edward W., Jersey City, N. J.
 Hogan, Thomas E., New York City.
 Hanson, Harry L., Butte, Mont.
 Hummel, Andrew J., New Ulm, Minn.
 Hewes, Frank L., Osceola Mills, Pa.
 Harding, Stedman, Tunkhannock, Pa.
 Johnson, James T., Wheeling, W. Va.
 June, Carrol A., Brandon, Vt.
 Keller, Paul H., Shelton, Conn.
 Kennard, Frank C., Clearfield, Pa.
 Kane, Thomas A., Brunswick, N. J.
 Kane, Michael J., Brunswick, N. J.
 Konow, Louis, Newark, N. J.
 Killmer, Carl P., Olean, N. Y.
 Klinghorn, Lyman J., Hardwick, Vt.
 Koehnlien, George C., Dwight, Ill.
 Lawrence, Thomas H., Corning, N. Y.
 Ledlg, Otto A., Newark, N. J.
 Loeble, Herman, Troy, N. Y.
 Lavelle, James A., New York City.
 Michels, Edward A., Rondout, N. Y.
 Minor, Halsey P., Farmer, N. Y.
 Mason, Metcalf P., Greenfield, Mass.
 Miller, Benjamin F., Gainesville, Fla.
 Manuel, Adonis A., Baton Rouge, La.
 Milano, Frank, New York City.
 Michael, Carl H., Talladega, Ala.
 McKnight, George F., Owen Sound, Ontario, Can.
 McKittrick, William B., Brooklyn, N. Y.
 Nacey, Harry M., Chicago, Ill.
 Ormsby, Rexford P., Norwich, N. Y.
 Plastow, Joseph W., Greenville, N. J.
 Parent, Herbert J., Lewiston, Maine.
 Pierce, Charles H., Pittston, Pa.
 Ashley, Charles P., Brooklyn, N. Y.
 Russell, David M., Waynesboro, Pa.
 Rhodes, Theodore S., Great River, L. I., N. Y.
 Reed, Howard B., Battle Creek, Mich.
 Reynolds, Ross A., Aurora, N. Y.
 Robinson, Leslie, East Quogue, L. I., N. Y.
 Rushmore, Albert E., Westfield, Pa.
 Ruggles, Archie E., Fowlerville, Mich.
 Rote, Charles A., Stockbridge, Mass.
 Scott, Charles T., Peekskill, N. Y.
 Siegel, Edward, Brooklyn, N. Y.
 Siefert, Fred A., Peoria, Ill.
 Shimp, J. Irvin, Lewistown, Pa.
 Trimble, Andrew P., Pittsburgh, Pa.
 Travis, Thomas R., Wilmington, Del.
 Trevithick, Thos., Jr., Wilkes-Barre, Pa.
 Vores, Alfred D., Jr., Brewster, N. Y.
 Williams, Arthur R., Cohoes, N. Y.
 Welander, Carl A., Moline, Ill.
 Walrond, Lorne B., Petoskey, Mich.
 Wilker, Clark H., Ionia, Mich.
 Wenger, Charles H., New Philadelphia, Ohio.
 Widmayer, Fred., Jr., Long Island City, N. Y.

DAY CORNICE CLASS, 1901-1902.

The following are the names of the pupils enrolled in the day cornice class:

Bauman, Herman, New York City.
 Elliott, Charles M., Kansas City, Mo.
 Kohout, Louis, New York City.
 Kastner, Albert, Louisville, Ky.
 Pehl, Max W., Poughkeepsie, N. Y.
 Schrumph, William T., West Hoboken, N. J.
 Wieber, Frederick E., Kingston, N. Y.
 Weeber, Otto J., Guttenberg, N. J.

A fine addition to the plant of the New York Trade School has lately been completed, in the erection of a central building containing on the ground floor the offices

of the school, with a spacious room on the second floor, which is now being fitted up as a library and reading room, for the use of the students. This new feature of the school is one that is likely to be greatly appreciated by the pupils, who will be able to use the library and reading room each day and evening of the week, and make it, in a measure, a club room. This meeting place is calculated to develop a fraternal and social spirit among the attendants at the school, which is highly desirable.

One of the most successful and interesting lines of work lately introduced in connection with the Trade School is the course of lectures for journeymen steam fitters and journeymen electrical workers, given each week by Arthur A. Hamerschlag. Mr. Hamerschlag reports that the attendance on these courses is considerably larger than ever before, and that the interest in them is constantly growing. Ninety-seven men are attending the electrical course and 76 the course on steam engineering. As these courses of lectures are not entirely free, a fee of \$1 being charged for each course, the large attendance proves a marked appreciation of the advantages offered, on the part of the men for whose benefit the lectures were initiated. Mr. Hamerschlag has inaugurated a very useful plan in connection with these lecture courses in preparing a printed synopsis of each lecture, which is distributed to the men and taken home by them.

ASSOCIATION OF MASTER PLUMBERS OF THE ATLANTIC COAST.

As a result of the call sent to the master plumbers of Delaware, Maryland, Virginia and the District of Columbia, 65 master plumbers met in Emerald Hall at Norfolk, Va., last Monday, for the purpose of organizing an Association of Master Plumbers. The delegates came from Wilmington, Del.; Washington, D. C.; Baltimore, Salisbury and Cumberland, Md., and Richmond, Lynchburg, Newport News, Portsmouth, Berkeley and Norfolk, Va.

The convention was called to order by James F. Traynor of Wilmington, Del., and a temporary organization was effected, with William H. Barnard of Norfolk, chairman; W. J. Kilby of Baltimore and Harry A. Miller of Wilmington, secretaries, and J. R. Guy of Norfolk, sergeant-at-arms. Chairman Barnard delivered an address of welcome, which was responded to by John Trainor of Baltimore. Committees on Credentials, By-Laws and Constitution and Rules were appointed, after which an adjournment was made. The Committee on By-Laws and Constitution submitted their report at a later session, and a constitution and by-laws, based on those of the National Association of Master Plumbers, were considered separately and adopted.

The name chosen for the organization was the Association of Master Plumbers of the Atlantic Coast. The new association will affiliate with the National Association. At the close of the routine business the following officers were elected for the ensuing year:

President, James F. Traynor, Wilmington, Del.

Vice-President, Lloyd Mitchell, Baltimore, Md.

Recording and Financial Secretary, J. S. Eaton, Wilmington, Del.

Treasurer, W. H. Barnard, Norfolk, Va.

Executive Committee: E. L. Guy, Norfolk; W. A. Rothrock, Baltimore, Md., and W. D. Nolan, Washington.

The place for holding the next annual meeting was left in the hands of the Executive Committee. On Tuesday the delegates were given an oyster roast at the Master Plumbers' Club, at Willoughby Beach.

EDWARD WOODS, who for nearly 40 years had been in the plumbing business at 38 Myrtle avenue, Brooklyn, N. Y., and who was formerly the partner of John H. Walker, died at his home, 341 Dean street, on Friday, December 6, of heart disease, in his fifty-fifth year. He leaves a widow and a daughter.

The Federal Boiler & Supply Company.

The Federal Boiler & Supply Company have been incorporated under the laws of New Jersey, with a capital of \$3,500,000. The new company are a practical consolidation of the Kellogg-Mackay-Cameron Company of Chicago; the Kewanee Boiler Company of Kewanee, Ill.; the Model Heating Company of Philadelphia, and the Uniontown Acme Radiator Company of Uniontown, Pa. The principal office of the new company will be in New York City. The directors of the company are: E. E. Baker, Clarence V. Kellogg, W. H. Pfahler, B. F. Baker, A. C. Mott; J. P. Dugger, James Mackay, W. A. Cameron, E. P. Mott, L. G. McCrum and W. D. Kellogg. The officers of the company are: Clarence V. Kellogg, president; W. H. Pfahler, vice-president, and B. F. Baker, treasurer. A large warehouse will be added to the plant of the Kewanee Boiler Company as one of the equipments of the new concern. The business of each of the concerns included will be managed separately as heretofore, so far as the solicitation and shipment of orders is concerned.

New Wrought Iron Pipe Mill.

The Carnegie Tube Company of Carnegie, Pa., have notified the trade that when they are in the market for wrought iron pipe they would be pleased to have the opportunity to quote on pipe of their manufacture. The mill is about ready to run, and they hope to be in successful operation before January 1. The company are now booking orders for January delivery. They will manufacture their own skelp, and it is their purpose to turn out a superior quality of strictly wrought iron pipe of standard weight. They think they are justified in making this statement in advance of actual operations, from the fact that their general manager, T. B. Everson, is a man of very wide experience in the manufacture of this kind of goods, and his acquaintance with men and methods has enabled the concern to construct a plant modern in every particular, which will be operated by men of proved ability and skill. The initial capacity of the plant will be from 60 to 80 tons of $\frac{1}{8}$ to 3 inch butt weld pipe per day. The officers of the company are A. A. Hutchinson, president; R. M. Vincent, vice-president; O. F. Grant, treasurer, and T. B. Everson, general manager.

The P. and S. S. League.

One-sided contests ruled in the Plumbing and Steam Supply League bowling tournament this week in New York. On Monday night the Brooklyn team of the Ronalds & Johnson Company won two games, the team of Thomas G. Knight losing two games and the Central Foundry Company team breaking even. The feature of the evening was the score of 181 by E. E. Benas of the Thomas G. Knight team. On Thursday night the Dimock & Fink Company team won both and the team of the H. P. Read Lead Works lost both of their games, the team of C. S. Locke & Smith winning and losing. The Dimock & Fink Company team scored 772 in their first game, to which F. Hogenaur contributed 194.

Quick Work.

One of the customers of the Makin-Kelsey Heating & Mfg. Company of Philadelphia recently requested them to examine the boiler and hot water heating plant in his city house, to see that it was all ready for winter use. Men were sent to the house with instructions to examine the radiators and connections, air valves and all piping, to clean the boiler and to examine it, then fill the boiler and the system and fire it, so as to be sure that it was in good working order. All of the preliminary work had been completed and the water was turned on to fill the system while the men stopped for dinner. When the system was filled an examination was made, when it was found that one section of the boiler, which was made by the Gurney Heater Mfg. Company of Boston, Mass., was cracked. This was immediately reported at the office and the Gurney Heater

Mfg. Company in Boston were called up by means of the long distance telephone at 3 o'clock in the afternoon. The section needed for repairs was ordered and shipped by express that day, and the next afternoon at 1 o'clock the boiler section was delivered at the residence and the men were set to work to make the repairs to the boiler. This episode speaks well for the enterprise of the Makin-Kelsey Heating & Mfg. Company, and for the promptness of the Gurney Heater Mfg. Company in attending to the wants of their customers.

Brass Goods Men Meet.

The annual meeting of the Association of Manufacturers of Plumbers' Brass Goods was held in Pittsburgh, Pa., in the early part of the week. After reaffirming the present prices, the question of a possible consolidation was discussed without action. After the following officers were elected, the meeting adjourned to meet again in Washington, D. C., with the jobbers and manufacturers on Thursday:

President, A. D. Sanders of Peck Bros. & Co., Chicago.

Vice-President, C. K. Sanborn of Haydenville, Mfg. Company, New York.

Secretary, W. T. Doyle, Milwaukee, Wis.

Treasurer, J. B. Calvledge of Hoffman & Billings Mfg. Company, Milwaukee.

About 40 concerns were represented at the meeting, among whom were the Bailey-Farrell Mfg. Company and the Standard Sanitary Mfg. Company of Pittsburgh.

The Barrus Apparatus for Testing Steam Pipe Coverings.

George H. Barrus, of Boston, Mass., installed at the Manhattan Railway power house in New York apparatus for ascertaining the efficiency of some of the various steam pipe coverings on the market. The testing plant was divided into two sections, one for coverings designed to stand on pipes carrying the higher pressure of 150 pounds per square inch, and the other for the lower pressure of 80 pounds. The size of pipe selected for the leading test was ordinary standard 2-inch steam pipe, and pipes 100 feet in length were used. Among the various coverings tested were: Johns' Asbestocel, New York Air Cell, Carey's Molded, Johns' Molded, Gast's Ambler Air Cell, Johns' Asbesto-Sponge Hair Felt, two and three ply; Asbesto-Sponge Felted Sectional, K. & M. Magnesia, Navy Brand Asbestos Fire Felt, and Watson's Imperial.

The lowest rate of condensation obtained on any of the 2-inch coverings of the 80-pound section was 13.46 pounds per hour, the highest 15.14 per hour. On the 150-pound section the lowest condensation was 10.47 pounds per hour, and the highest 14 pounds per hour, all these figures being the average rate for a period of about 7½ hours' continuous run. The test seems to have demonstrated conclusively the value of testing coverings for steam pipes.

Death of R. J. O'Crowley.

R. J. O'Crowley died at his home, 12 Lombardy street, Newark, N. J., on Thursday night, December 5, after an operation for appendicitis. Mr. O'Crowley was in the fifty-fifth year of his age and was born in Cork, Ireland. He came to the United States when he was 19 years of age and learned the plumbing trade, after which he entered into a partnership with Dennis Rutherford, succeeding to the business when Mr. Rutherford died some years ago. Mr. O'Crowley was a member of the Newark Board of Trade, the Master Plumbers' Association, the Orpheus Club and several secret societies. He married Sarah J. Rutherford, who survives him, with two sons and two daughters. He was buried from St. Patrick's Cathedral in the Cemetery of the Holy Sepulchre.

GOULD & NOWLEN, Bath, N. Y., bid \$1662 and secured the contract for remodeling the heating system in the Court House in that town.

Heating and Plumbing Notes.

THE regular quarterly meeting of the Association of Manufacturers and Jobbers in Plumbers' Supplies East of the Alleghany Mountains was held in Washington, D. C., this week. The meeting was devoted to discussing various matters relating to trade interests with a view to establishing a more satisfactory market for the coming year.

THE VANDERMAN PLUMBING & HEATING COMPANY of Willimantic, Conn., have an order for all the Valve Castings to be used in the big twin vessels under construction at the works of the Eastern Shipbuilding Company, at Groton, Conn.

C. S. MERSICK & Co., New Haven, Conn., recently conducted a comparative test of the anti-siphonic qualities of a number of different Lavatory and Sink Traps now in general use, demonstrating the high efficiency of a Trap for which the house are agents. It was found that with this Trap water could not be siphoned out below the levels of the flange, and that it was impossible for the air to get back through the pipes, as with the modifications of the common S Trap and a number of patented Traps.

THE contract for plumbing the new office building of the Union Hardware Company, at Torrington, Conn., has been let to W. H. Morrison of that place.

RICHARD SIM has sued the Allegheny Heating Company of Allegheny, Pa., for \$25,000 for the death of his wife, \$3000 for the destruction of his home and \$500 for its furnishings. The plaintiff lived on Buchanan avenue, Allegheny, and upon November 7 last, it is charged, a leaking main was responsible for the filling of the cellar with gas, which resulted in an explosion, causing the death of Mrs. Sim and destroying the plaintiff's property.

THE heating contract for a new eight-room school house at Woonsocket, R. I., has been awarded to the John F. Mulvey Plumbing & Heating Company of that city, and the contract for the plumbing to the Samuel Jackson Company.

THE contract for plumbing the new Town Hall in West Hartford, Conn., has been awarded to Hanlon & Murphy, and the heating contract to the Hartford Heating Company.

A MASTER PLUMBER of Cleveland, Ohio, has appealed to the local Board of Control for protection against the plumbing inspector, whom he charges with persecuting him. The plumber admitted, however, that on several occasions he had done work without filing plans or securing a permit.

FRANCIS BROTHERS & JELLETT, INCORPORATED, Philadelphia, Pa., bid \$2900 and secured the contract for installing a heating system at 1020 Filbert street, Philadelphia.

A LETTER from the Ideal Mfg. Company, Detroit, Mich., informs us that the suit brought against them on the charge that their Ideal Volunteer Water Closet Flushing Device was an infringement of other patents did not come before a court, as consent was given to a decree dismissing the bill of charges.

THE first calendar of the season has reached us through the courtesy of H. H. Beals, 51 Cliff street, the New York representative of the Wm. Powell Company of Cincinnati, Ohio. The date leaves show the various Valves, Oil Cup Bibs, Water Gauges, Service Cocks and the water, steam and gas iron and brass goods made by the house. These leaves have a small monthly calendar in the upper corner, while a weekly leaf gives the days and dates in large 2½-inch figures. The leaves are attached to a card showing Powell's Star Regrinding Valve in bronze against a red star on a blue ground, which has in white the hands of America, Europe, Africa and Asia pointing to the Valve. The address of Mr. Beals appears on the card in blue letters on a white ground.

THE CHARLES PARKER COMPANY, Meriden, Conn., inform the trade that they are now manufacturing the entire line of Plumbing Material formerly manufac-

tured by the Meriden Malleable Iron Company. They found by investigation that the Meriden Malleable Iron Company's general line of Legs, Brackets and many of their specialties are among the finest manufactured in this country. They are also aware that many new articles are required to freshen the line, and it is their purpose to add everything necessary to make it complete. A variety of articles will be added to the line not before made by the Meriden Malleable Iron Company. At the present time the company are at work on this new material, and hope to be able to have such articles ready for shipment early in the coming year. A catalogue of their line of goods will be ready for distribution early in 1902.

THE HAYS MFG. COMPANY, Erie, Pa., have issued an announcement, in which they say that they have rebuilt a new plant above the ruins of the former one which was wrecked by a boiler explosion on October 9. They claim to be better equipped now than ever before, having as perfect a brass foundry as can be constructed. They are out after business again, and as their territory is large it will take their traveling representative some time to convey the good news in person, lest the trade should forget then in the meanwhile they make this advance announcement. It adds, "Don't think we are out of existence, but remember we are doing business at the old stand, and solicit a continuance of your patronage."

THE ZERO VALVE & BRASS MFG. COMPANY, Buffalo, N. Y., say that for some time they have been manufacturing the Phoenix Flue Cleaner for the Hubbard Mfg. Company, and have now taken the selling agency. To persons handling this style of supplies they will send a sample with a view of obtaining their orders. They state that there are a great many Flue Cleaners on the market, a few of them being good and others bad. The Phoenix, they claim, is one of the good ones, and they recommend and guarantee it as satisfactory in every way. The company carry these goods in stock from 1½ to 4 inches, inclusive, in ¼-inch sizes, and from 4½ to 6 inches, inclusive, in ½-inch sizes.

THE HUMPHRIES MFG. COMPANY, Mansfield, Ohio, are now ready to take care of any specifications that they may receive for Pumps and Cast Iron Sinks. Since the fire, which occurred on June 7, they have been busily engaged in rebuilding the destroyed portions of their factory, and now believe they have as modern and well equipped a factory as any. Their foundry has been enlarged and rearranged, so that they can carry on the manufacture of their different lines without any confusion and without one line interfering at all with the other. The company refer to the patience and indulgence with which they have been favored by their customers, and hope to repay them by prompt filling of orders in the future.

THE OHIO BRASS & IRON MFG. COMPANY, Cleveland, manufacturers of Plumbers' Brass Goods, report that the volume of their business has increased fully 20 per cent. this year.

A NUMBER of the master plumbers of Chicago have entered suit against the city for the recovery of license fees which were paid during this year in compliance with an ordinance of the City Council. As the Supreme Court of the State subsequently declared the collection of these license fees illegal, the plumbers are now taking steps to have the payments returned.

THE citizens of Quincy, Ill., are working to secure the location in that city of a factory for the manufacture of plumbing supplies. The names of the projectors of this enterprise are not disclosed, but it appears that the citizens were asked to raise a subscription of \$30,000 toward the capital stock of the company. This sum has been secured and it is now expected that the establishment will be erected and another important industrial undertaking will be added to the list of factories located at Quincy. That city has been quite fortunate the past year in securing additional industries which will give employment to a large number of workmen.

THE HOOD MFG. COMPANY of Carthage, Mo., have bought a new building on Main street, into which they

will move their Faucet manufacturing machinery and equipment. The company have outgrown their old quarters and the new building will give them increased facilities. New machinery will be added to increase the output.

THE SMITH & ABBOTT COMPANY of Portland, Maine, are installing a steam heating plant in the Odd Fellows' Block at Rumford Falls, Maine.

New Firms and Changes.

H. L. PARSONS AND A. J. HEAD have opened a plumbing shop in the Wells Block, Prescott, Ariz.

THE plumbing and steam fitting firm of Munro & McGlynn of Whittenton, Mass., has been dissolved by the withdrawal of Mr. Munro. The business will be continued by Andrew McGlynn.

THE UNIVERSAL LIGHT & FIXTURE COMPANY have been incorporated at Huron, S. D., with a capital of \$300,000 by W. M. Smith, O. C. Smith and Philip Lawrence.

New Publication.

CONTRACT AND ESTIMATE RECORD BOOK FOR PLUMBERS. By B. H. Jessup. Pocket edition, 200 pages, arranged for 50 estimates. Size, 3½ x 8 inches (oblong). David Williams Company, publishers, 232-238 William street, New York. Flexible cloth; price, 50 cents.

Estimate books, now largely in use by plumbers, are designed to reduce the labor involved in preparing estimates on jobs and to obviate the risk of omitting items in figuring, which often results in loss to the plumber. This is an improved edition of an estimate book in size suitable to be carried in the pocket. It contains 50 complete forms for estimates, with a space at the head of each form for entering the date and the name of the person to whom the estimate is furnished. In preparing estimates, the plumber usually finds it necessary to go over a long list of items of materials. Figuring these items from memory or from memoranda is believed to be an unhandy and unreliable method, and this book, therefore, meets a well defined want in providing a means of keeping track of the cost of work and affording a systematic record. The form of estimate employed embraces a list of all material used in any ordinary house with each item in its proper classification. Parallel columns give space for entering the cost of each item, which will enable the estimator to easily add the total.

Mr. Jessup has also prepared a large sized Plumbers' Estimate Book for office use, and a Steam and Hot Water Heating Estimate Book, information of which can be obtained from the publishers.

Moved by the recent terrible accident on the Wabash Railroad, George H. Barbour of the Michigan Stove Company has written a strong letter to the *Detroit Free Press*, urging the necessity of legislation to prevent such serious accidents in the future. Mr. Barbour expresses the opinion that the first important thing for railway officials to consider is that of the safety of their passengers; secondly, their comfortable accommodation, and, thirdly, speed. He believes that the law should regulate the speed of passenger trains, so as not to allow them to exceed 10 miles an hour when passing a siding where it is expected to meet another train, instead of running, as they do now, at 60 miles an hour.

THE G. DROUVE COMPANY, Bridgeport, Conn., have taken some important contracts lately and are very busy at their plant. They are now getting out Skylights for the Pittsford-Florence Marble Company, Pittsford, Vt.; Copper Cornices for the Pierce Temporary Home in White Plains, N. Y.; Skylights and Galvanized Iron Work for the new plant of the Port Chester Bolt & Nut Company, Copper Work for the Port Chester Trust Company's new building, the new Auerbach residence in Far Rockaway and a fine residence in Lenox, Mass., for R. W. Patterson, and are finishing up the Copper Work on two hotels in Palm Beach, Fla., and a racquet court at Tuxedo Park, N. Y.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

FROST ON WINDOWS.

From W. I. S., Lynn, Mass.—In last week's *Metal Worker* I noticed how "R. C." keeps frost from forming on his show window. The method he employs is all right and works well, but his theory that the cold air enters at the bottom of the window, fills the inclosed window space and crowds out the warm air through the holes at the top of the window is not in accordance with my experience. In real cold weather there is always a current of air circulating behind a window. The warmer air in the room or window space, as it may be, naturally is near the ceiling. When this strikes the window

Frost on Windows.—“W. I. S.’s” Theory of Air Current Behind Show Window.

it is immediately chilled and drops rapidly, keeping very close to the glass until it gets to the floor. The force of this descending current of air can frequently be felt with the hand, and can be most easily and plainly observed by blowing a little smoke from a cigar near the window. The smoke will be drawn in by the strong downward current, as soon as it gets near the window, and will fall to the floor. I do not believe that boring holes at the top and bottom of a window will prevent the action of this strong air current, but that this current would suck cold air through the top holes and let some cold air escape out of the lower holes. The accompanying illustration shows my theory as to the movement of the air.

Note.—It will be interesting if other readers of *The Metal Worker* will give their ideas and experiences on this subject.

LIFT PUMPS WITH LONG SUCTION PIPES.

From T. P., Newtown, N. J.—I have read the letter of "C. R.," in *The Metal Worker* of December 7, and would state that, in my experience, if the foot valve is tight there is no occasion for a check valve between the pump and the foot valve. When the suction pipe is so long some difficulty will be found in working the pump if attempt is made to lift water 25 feet. It will be necessary, however, for the piping to be securely fastened and the pump to be firmly fixed, so that the force required to operate it will not loosen it from its fastening. The labor in the operation will be decreased as the

lift is decreased. There should be no serious difficulty, however, in getting the pump to operate at 25 feet lift if the work is carefully done and a good pump is used. It will be necessary to use a pump having a good, durable valve and cylinder.

From G. E. S., East Stroudsburg, Pa.—In reply to the inquiry of "C. R.," in *The Metal Worker* of December 7, I would say that there will be no difficulty with his pump working all right if arranged as shown in the sketch. An air chamber near the cylinder will be beneficial, as the flow of water will be more uniform to the pump and the jarring will be reduced somewhat. A 1½-inch pipe will be better for the suction pipe than 1¼-inch, as there will be less friction. A check valve near the cylinder is unnecessary, but a good foot valve should be used.

MAKING SEWER CONNECTIONS.

From P. R., Phillipsburg, N. J.—I shall be glad to secure information in reference to the methods of making sewer connections in different cities, where both terra cotta sewers and sewers built of brick are used.

Is it best to use extra heavy cast iron for connections with a sewer or is there no objection to the use of terra cotta pipe?

If terra cotta pipe is used should it be glazed, and how should the house sewer connect with the street sewer, at the ordinary level of the flow in the sewer or above it?

Should the sewer connection pitch downward at the point of connection?

How much grade should be given to the sewer from the house to the street sewer; or, rather, what is the least grade that will insure successful results?

Is there any objection to the use of the front wall trap, and how is the best way to protect its seal?

Does not the settling of the front wall of a building oftentimes interfere with the drain pipe at the point where it passes through it, and is there not some method of protecting this pipe without permitting surface water running down along the outside of the wall and into the cellar through the opening where the drain pipe passes through?

I have asked a number of questions, and I hope that those who have had experience will relate what they have found to be the best in their practice, as the information will be of special advantage to me at this time, while I feel sure that many other readers of *The Metal Worker* would be glad to have the established customs of the trade explained, with the reasons for their becoming generally used. I also know that in different sections of the country different customs prevail, and I feel certain that *The Metal Worker* will welcome a presentation of such sketches and explanations as men who are interested in substantial sanitary work can furnish.

PAINT FOR GALVANIZED IRON.

From B. F. K., Desplaines, Ill.—In answer to the inquiry of "B. B. C.," in *The Metal Worker* of November 30, I would suggest that he will find the following method of treating galvanized iron surfaces before painting satisfactory: They should first be cleaned or prepared with the following solution: Dissolve 2 ounces of chloride of copper, 2 ounces of nitrate of copper and 2 ounces of sal ammoniac in 1 gallon of water, and to this solution add 2 fluid ounces of hydrochloric acid. Cover the surface of the galvanized iron with the solution and it will turn to a black color, which, on standing and drying over night, will turn a light gray color. If the surface is then primed with a coating of red lead, thinned with equal parts of raw oil and turpentine, he can rest assured that paint will hold to it like grim death.

From W. N., New York.—Replying to the inquiry of "B. B. C.," in *The Metal Worker* of November 30, for paint that will stick to galvanized iron, I would advise him to allow the galvanized iron to be exposed to the weather about one week. Then give it a ground coat of metallic paint mixed in pure boiled linseed oil. That this will adhere to the galvanized iron I know from experience. When perfectly dry put on any desired color.

UTILIZING WASTE HEAT.

From Northern Plumber, Vermont.—I have read the inquiry of "Southern Plumber," in *The Metal Worker* of December 7, and congratulate my Southern contemporary on his desire to economize. I have thought that the disposition to economy and thrift was patent in my neighborhood, but am glad to see that the New England influence is extending. The problem he presents is one on which I doubt if there is much information that can be used as a guide. I have heated radiators from the regular water backs and boilers connected with kitchen ranges, also from special pipe coils, and have used the smoke pipe of hot air furnaces for heating water to be circulated through radiators placed in rooms which were subject to the influence of strong winds.

The proposition which he presents is somewhat different from any of these, and the success depends largely on the manner in which the range is run. If it is run so that the draft is not checked by removing the covers and allowing cool air to be drawn up the chimney, success may attend such an experiment. If the covers are not off the range most of the time and the draft is kept open the gases which rise from the fire will be hot and their heat will be absorbed by the water in the coil, and

Utilizing Waste Heat.

this can be circulated through the radiator. A much larger pipe coil, however, will be required in connection with the smoke pipe from a range than would be necessary with the pipe from a hot air furnace. It is doubtful even then if the water would be raised to as high a temperature as is usual in hot water heating systems. In consequence I would provide 1 foot of surface in the radiator in each of the bathrooms for each 25 cubic feet of space it contains. This would make 48 feet of surface in each of the rooms.

Possibly some benefit would attend the use of a larger radiator in the bathroom on the first floor, inasmuch as the water would be cooled in passing through the upper radiator. Assuming that 100 feet of radiation will be used in the two rooms and piping, a pipe coil must be made that would be large enough to heat the water they contain. It is doubtful if 1 square foot of surface in such a pipe coil will heat the water to a sufficiently high temperature if it is expected to take care of more than 10 feet of surface. By dividing the 100 square feet of radiating surface by 10 it will be found that the coil in the smoke pipe must expose 10 square feet of surface. If it is made of 1-inch pipe it will require about 30 lineal feet. The coil should be made very open, so that the hot gases can pass around all sides of the heating coil. It would be better if the section of pipe in which this coil is to be placed was made at least 10 inches in diameter, having a 7-inch pipe collar at the top and bottom. This will enable the coil to be made 7 inches in diameter on the inside.

Now, my Southern friend states that the pipe coil must be placed in the second joint of the pipe above the stove. This is not the best place for it. It should be in the first joint by all means, both for good heating and to insure a good circulation through the radiators. If located so high it will seriously impede the circulation of the water through the two radiators, and may inter-

fere with the circulation to such an extent as to defeat the object of the whole outfit. I would suggest supplementing the heating coil in the pipe by another in the fire. If two holes are drilled in the range a loop of the pipe can run through the lower hole into the fire chamber, across the long side, and then, with a close return bend, run back again out of the upper hole before it connects with the heater in the smoke pipe. This can be done without disadvantage to the general operation of the range, and it will add materially to the efficiency of the heating arrangement proposed. It will only be necessary to cut the fire brick down a few inches to allow this pipe coil in the fire chamber to lie against the oven and to have the fire lie against it, so that however the range may be operated some heat will be transmitted to the water heating system through the loop of pipe lying in direct contact with the fire.

PREPARING GALVANIZED IRON FOR PAINTING.

From J. & D., Indianapolis, Ind.—We found in one of the back numbers of *The Metal Worker* and tested a very useful receipt for coating galvanized iron to prevent the paint upon it from peeling off. We now have occasion to paint a house which has been covered all over with galvanized iron and know that the solution we used was satisfactory. We wish to use it again, but cannot find it, and shall be glad to be informed in what issue it appeared.

Note.—Our correspondent probably refers to the solution given in *The Metal Worker* of October 21, 1899, which is given in this issue from another correspondent who has tried it. Another article on the same subject was presented in *The Metal Worker* of November 25, 1899. Articles in reference to painting sheet zinc were given in *The Metal Worker* of March 11, 1899, and April 1, 1899. We shall be glad to have our correspondents report the results after they have painted this galvanized iron sheathed building, and sufficient time has elapsed to test the holding powers of the paint.

WANTS SUBSTITUTE FOR EARTH CLOSET.

From G. J. D., Minneapolis, Minn.—I shall be pleased to learn of a convenient portable and sanitary substitute for the city water closet for use in the country. I know of nothing better now than the earth closet, which is not satisfactory. If any of the readers of *The Metal Worker* have knowledge of such a device as I desire I shall be glad to learn of it through its columns.

REPAIRS FOR MATCHLESS STOVES.

From B. B. Christie, Dayton, Ohio.—I should like to learn where I can secure repairs for the Matchless stoves and ranges, that were formerly made by Duncan & Co. at Sharon, Pa. I have addressed letters to Duncan & Co. at Sharon, Pa., and the letters have been returned.

WHAT IS THE BEST ROOF COVERING FOR ROUNDHOUSES?

From W. M., Suffolk, Va.—Will some of the readers of *The Metal Worker* give their views as to how to construct the most lasting roof for a roundhouse? I should like to know whether iron or wood framing is best to withstand the sulphurous gases, and whether metal, slate or felt roofing is most serviceable?

GALVANIZED IRON ROOFING ON THE SEA COAST.

From Roofer, Atlantic Sea Coast.—We are called upon to place the roof on a large factory building which is located on the Atlantic sea coast, where the salt atmosphere is looked upon as especially destructive to iron. Owing to the size of the building a roof of cement or slate would necessitate a very expensive framing and our customer desires to learn of the durability of galvanized iron roofing under the circumstances. We would be glad to have *The Metal Worker* or its readers give their views on the subject.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin is dull and weak, ruling about $\frac{1}{4}$ c. lower.
Copper is unsettled, and retail prices are inclined to soften.
Pig Lead is unchanged.
Spelter is active, and rules $\frac{1}{8}$ c. higher.
Antimony is unchanged.
Nickel continues firm and active.
Aluminum is active at former prices.
Tin Plates are quiet and unchanged.
Sheets are still scarce and in heavy demand, with supplies below demand.
Sheet Copper is firm in price, with fair current demand.
Pig Iron is strong and active; prices on Southern Irons tending upward.
Hardware is moving in large volume, and prices are steady.
Plumbers' Supplies are in good demand for the season, with strength in prices for all lines.
Scrap, Brass and Copper are about $\frac{1}{2}$ c. lower.
Tin Cans have been reduced in price.
Wrought Iron Pipe prices are firm, with continued good demand.
Screws are somewhat irregular in price.
Wire Nails are in moderate demand, with prices showing some irregularity.
Cut Nails are moving in fair volume, with prices unchanged.
Wire prices are uneven.
Window Glass is dull, and lower prices are looked for.
Linseed Oil market is unsettled.
Spirits Turpentine is firm and a shade higher.

THE PIG IRON MARKET.

NEW YORK.—The market has been quiet and firm, no large transactions being noted in this district. We quote: No. 1, \$16.35 to \$17.50; No. 2 X, \$15.65 to \$16; No. 2 Plain, \$15.15 to \$16; Tennessee and Alabama brands, No. 1 Foundry, \$16; No. 2 Foundry, \$15.25; No. 1 Soft, \$16; No. 2 Soft, \$15.25; No. 3 Foundry, \$14.75; No. 4 Foundry, \$14.25.

CHICAGO.—The general demand for Pig Iron is very good, and special causes are contributing to an unusually heavy trade in certain classes of Iron. A sharp demand is especially noted for Lake Superior Charcoal, which has been selling up to \$19, and even \$19.50. Numerous inquiries are in the market, several being for quantities of Foundry Iron ranging from 1000 to 3000 tons. The local furnaces are quoting cautiously, and will continue to do so until the question of a sufficient fuel supply is satisfactorily settled. Many orders for deliveries earlier than April or May are being passed, on account of the fuel uncertainty. The Southern furnace companies, being in better position with regard to fuel, are making the most of the opportunities now prevailing. An advance of 20c. per ton is announced on the freight rate on Southern Iron by the railroad companies north of the Ohio River, to go into effect January 1. We quote as follows:

Lake Superior Charcoal.....	\$18.00 to \$19.00
Local Coke Foundry, No. 1.....	16.00 to 16.50
Local Coke Foundry, No. 2.....	15.50 to 16.00
Local Coke Foundry, No. 3.....	15.00 to 15.50
Local Scotch, No. 1.....	16.00 to 16.50
Ohio Strong Softeners, No. 1.....	17.60 to 17.85
Southern Silvery, according to Silicon.	16.15 to 16.40
Southern Coke, No. 1.....	15.65 to 16.15
Southern Coke, No. 2.....	15.15 to 15.65
Southern Coke, No. 3.....	14.65 to 15.15
Southern Coke, No. 1 Soft.....	15.65 to 16.15
Southern Coke, No. 2 Soft.....	15.15 to 15.65

PHILADELPHIA.—The heavy recent purchases give the market at present a very tame appearance as compared with its recent condition. Prices are firmer, however, and sales during the past few days average a full 25c. per ton advance on the prices ruling the previous week. Most of the recent business is for immediate shipment. Prices are rather hard to quote with exactness. When deliveries are easy, both as to time and distance, the buyer can do better than the one who has to pay for a long haul, but the range for Philadelphia and nearby points will be about as follows: No. 1 X Foundry, \$16.25 to \$16.50; No. 2 X Foundry, \$15.75 to \$16.25; No. 2 Plain, \$15.35 to \$15.65.

PITTSBURGH.—The United States Steel Corporation have bought something over 20,000 tons of Bessemer Iron from the Furnace Association at \$15.25, at Valley furnace. This, however, is absolutely the minimum of the market, as sales of Bessemer Iron are being made at \$15.75 and up to \$16, at furnace. There is a scarcity of Bessemer for prompt shipment, and sellers can get almost any price they ask. Foundry Iron is also active and prices are higher, No. 2, for prompt shipment, having sold at \$16.25, Pittsburgh. We quote No. 1 Foundry at \$16.50 to \$16.75; No. 2 at \$16 to \$16.25, f.o.b. Pittsburgh. Heavy purchases of Foundry Iron have been made for delivery running all through next year, and some of the furnaces that produce Foundry grades report that they are pretty well sold up for the first half of the year.

CINCINNATI.—With no material change in conditions the week closes on a strong and regular market. Trade is somewhat quiet, and not very many orders for over 1000 tons have been recorded, but there is a good run of minor transactions, making a fair tonnage in the aggregate. If there was any standard Iron for immediate delivery it would be taken at once in considerable quantities, but the market is barren in this line; indeed, Iron for next quarter's delivery is getting quite scarce, with a good strong undertone. Holiday conditions will likely be the order of the market for the next few weeks. Higher prices are not immediately expected. Northern Irons are advancing a little ahead of Southern stock. We quote, f.o.b. Cincinnati:

Southern Coke, No. 1.....	to \$15.00
Southern Coke, No. 2.....	to 14.25
Southern Coke, No. 3.....	to 13.75
Southern Coke, No. 4.....	to 13.25
Southern Coke, No. 1 Soft.....	to 15.00
Southern Coke, No. 2 Soft.....	to 14.25
Southern Coke, Gray Forge.....	to 13.25
Southern Coke, Mottled.....	to 13.25
Ohio Silvery, No. 1.....	\$15.60 to 16.10
Ohio Silvery, No. 2.....	15.10 to 15.60
Lake Superior Coke, No. 1.....	to 16.60
Lake Superior Coke, No. 2.....	to 16.10
Lake Superior Coke, No. 3.....	to 15.60

ST. LOUIS.—While an unusually good volume of inquiry is noted in the Pig Iron market, the volume of actual sales is considerably lighter, but this condition is the usual one at this period of the year. The market as a whole presents a very strong appearance. We quote as follows for cash, f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$15.50 to \$15.75
Southern, No. 2 Foundry.....	14.75 to 15.00
Southern, No. 3 Foundry.....	14.25 to 14.50
Southern, No. 4 Foundry.....	13.75 to 14.00
No. 1 Soft.....	15.25 to 15.50
No. 2 Soft.....	14.75 to 15.25

METAL MARKET.

NEW YORK, December 13, 1901

Pig Tin.—Business throughout the week has been very dull. The market has been in the buyer's favor, but consumers show little inclination to do business. After the rapid declines of last week a slight reaction set in early in the present week, to be followed by another decline, the market closing weak and dull. Jobbers' prices for small lots of Straits Pig are a trifle be-

low those ruling a week ago, 26c. to 26½c. being about the present average range.

Copper.—That certain large consumers and the principal producers are most anxious to bring about a termination of the present demoralized condition is very evident. Producers want to get out of the situation as comfortably as possible, and the consumers want to see a steady, stable market. There are, as yet, however, no signs of any settlement between these parties. Production is going right on and consumption is only according to the actual needs of purchasers. The slump in Amalgamated Copper stocks in Wall street has emphasized the unsettled feeling among the trade, who are purchasing metal very sparingly, in the anticipation of a possible early break in prices of Copper. With the natural dullness of the market incidental to the last few weeks of the year, the strained conditions existing conspire to limit the business in Copper very materially. Retail prices are slightly lower, Lake Ingot in small lots being quoted at 17c. to 17½c. per lb.

Sheet Copper.—The current consumptive demand for Sheet Copper continues to be of good proportions, but is not so large as it has been heretofore. The shaky condition of the market for the raw material tends to make consumers of Sheet Copper disinclined to purchase anything beyond the limits of their actual current requirements. Nevertheless, a goodly amount of material is going into consumption and prices show no signs of weakness. Small lots of Sheet Copper from store are quoted on the basis of 21c. per lb.

Pig Lead.—Notwithstanding the announcement that an agreement had been arrived at between the American Smelting & Refining Company and the miners, it is stated in the trade, on good authority, that the miners have not agreed to curtail production. It is held that while the conference may be over, an agreement has not been reached, and especially an agreement that will tend to better the situation. The market conditions remain unchanged, transactions being on a limited scale, and prices without variation. American Plg in small lots is quoted at 4.55c. to 4.60c. per lb. St. Louis advices report the same order of conditions ruling in the Pig Lead market in that center, with no change in prices.

Spelter.—Spelter for spot delivery is considerably stronger here, and the volume of business is said to be good. Jobbers prices for good Western brands in small lots have been advanced about ½c. per lb. to 4½c. to 4¾. St. Louis advices report a quieter feeling in the Spelter market at that point, with prices having reacted slightly on the lighter demand, but holding very firm around the present level.

Sheet Zinc.—The usual demand for Sheet Zinc is noted by jobbers who quote 600-lb. cask lots at 6¾c. per lb., and smaller quantities at 7¼c.

Antimony.—No change has taken place in this metal. Cookson's in small parcels is quoted at 10½c. to 11c., and Hallett's at 8½c. to 9c. per lb.

Nickel.—Is unchanged, prices continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—An active demand for Aluminum continues, and prices remain at 37c. per lb. for small lots of No. 1 Ingot guaranteed 99 per cent. pure 35c. for 100-lb. lots.

Tin Plates.—Conditions in the Tin Plate market show no change from those prevailing for the past few weeks. The approach of the end of the year is always a dull season in this trade, and the present is no exception to the rule. The demand is of quite moderate proportions, and consists mainly of small orders for present use. Deliveries are coming in with rather more freedom, but stocks of the more popular sizes of Plates are still light. Prices hold at about last week's level. American Bessemer Coke Plates, I C, 14 x 20, are selling in small lots, in New York and corresponding points, at about \$5.25 to \$5.75 per box.

Sheets.—The demand for Sheets continues very active, and deliveries are still considerably behind hand. A good many new contracts are being placed, in some cases for deliveries running through the first half of

next year. Some of the new Sheet capacity is now coming into the market, and a few of the new mills are going after orders very aggressively. Prices continue steady in consequence of the short supply of Sheets, No. 27 One Pass Cold Rolled Soft Steel Sheets being quoted by jobbers at 4c. to 4.05c., and Galvanized Sheets at 65 to 65½ per cent. off the list.

Chicago advices are as follows: The supply of Sheets has not yet been restored to its normal condition. The leading Sheet manufacturers have by no means caught up with their back orders, and the independent mills starting up hardly get into the market until they are filled with orders taking their output for 60 days or more. Large consumers are eagerly seeking a better supply and are satisfied to take whatever they can get. The jobbing trade is still suffering from a shortage of Wood's Smooth Sheets and Planished Iron, for which a special demand always exists. Mill shipments of No. 27 Black Sheets are quoted at 3.15c. to 3.40c., Chicago, and small lots from stock are selling at 3.50c. to 3.70c. Galvanized is in somewhat better supply and small lots are selling at 70 to 70 and 2½.

Old Metals.—The conditions in the Copper market have created a weak tendency in the market for Scrap Copper and Brass, which are quoted lower. Otherwise there has been no change in the market for Old Metals. Demand is of moderate proportions. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb. 14¼c.
Light and Tinned Copper.....	per lb. 12¼c.
Heavy Brass.....	per lb. 9 c.
Light Brass.....	per lb. 7¼c.
Lead.....	per lb. 4 c.
Tea Lead.....	per lb. 3½c.
Zinc.....	per lb. 2¾c.
No. 1 Pewter.....	per lb. 17½c.
No. 2 Pewter.....	per lb. 8½c.
Tin Plate Scrap, per gross ton.....	\$6.00 to \$6.50
Wrought Iron Scrap, per gross ton.....	10.50 to 11.00
Heavy Cast Scrap, per gross ton.....	10.25 to 10.50
Stove Plate Scrap, per gross ton.....	7.75 to 8.00
Burnt Iron, per gross ton.....	5.00 to 5.50

CHICAGO REPORT.

Scrap Iron and Steel.—Business is quiet, as large consumers are endeavoring to force prices lower, especially on material suitable for use by rolling mills. We quote dealers' buying prices in carload lots, Chicago delivery, as follows:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast.....	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	8.00 to 8.25
Burnt Iron and Grate Bars.....	5.50 to 6.00
Sheet Iron and Hoops.....	6.00 to 7.00
Plow Steel.....	... to 10.00
Breaking Stock.....	9.00 to 10.00
No. 2, such as Shovels, Hoes, &c.....	... to 7.00
Old Boilers—whole (Iron).....	6.50 to 7.00
Old Boilers (Iron) cut in single Sheets and Rings.....	9.00 to 10.00
Old Gas Pipe and Boiler Tubes.....	10.50 to 11.50
Cast Borings.....	4.50 to 5.00
Turnings.....	9.50 to 10.00
Horseshoes.....	... to 13.00

Old Metals.—The fear of lower prices on Ingot Copper is causing holders of Old Metals to try to dispose of them, and they are making concessions in prices. Dealers quote buying prices on small lots as follows:

	Per lb.
Copper Wire and Heavy.....	13¾c.
Copper Bottoms.....	12¾c.
Copper Clips.....	13½c.
Red Brass.....	13 c.
Yellow Brass.....	9¼c.
Red Brass Borings.....	11 c.
Yellow Brass Borings.....	8 c.
Light Brass.....	7¼c.
Pipe Lead.....	4 c.
Tea Lead.....	3¾c.
Zinc.....	3 c.
Tin Foil.....	22½c.
Pewter, No. 1.....	18 c.
Pewter, No. 2.....	15 c.

Old Rubber.—The demand from consumers is light and stocks are increasing. We quote as follows:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7¼c.
Rubber Car Springs.....	5½c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	6¾c.
Black Rubber.....	4¼c.
White Rubber.....	5¼c.

Rags.—Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at 75c. to 85c. per 100 lb. in any quantity.

Anthracite Coal.—All kinds of Coal are in strong demand, while the supply is short, owing to the scarcity of cars. Prices are unchanged, as follows:

	Grate.	Egg and Stove.
Chicago	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

THE HARDWARE TRADE.

There is a falling off in the volume of business, as usual at this time. Current shipments are for the most part of holiday and winter goods, which are hurried along to meet the immediate requirements of merchants. In these lines trade is active and indicates in its volume and the character of the goods moving an enterprising and prosperous condition among the trade at large. There is a good deal of business being done by the jobbers throughout the country in supplying the smaller trade, and they are also buying for next year's requirements. The orders which are thus coming in to manufacturers are very satisfactory, showing confidence on the part of merchants in the stability of prices and in the continuance of existing prosperous conditions. Comparatively few manufacturers have full stocks of goods on hand, nearly all of them welcoming something of a relaxing in the demand which will permit them to get in shape for next year. There is a better supply of some lines, especially of heavy goods, such as Pipe, Sheets, Plates, &c. Orders for season goods are being booked rapidly and many anticipate something of a scarcity in some important lines. Prices generally are steady and firm. Steel Goods and Screws are in an unsatisfactory condition and low prices are ruling. Scythes seem to have settled to their level. Wire Nails and Wire are regarded with suspicion, and the trade, unless covered by some kind of special understanding with the manufacturers, are buying very cautiously. The general situation is regarded as very satisfactory and the outlook for business as excellent. The year draws to a close with conditions that should contribute to the enjoyment of the holiday season.

NOTES ON PRICES.

Wrought Iron Pipe.—Although there has been no change in the price of Wrought Iron Pipe at the mills, there is a feeling that the advent of several new and independent mills will bring about a change in the market. The jobbing trade seem to be of the opinion that no change will occur much before the beginning of March or April of next year. It is argued that the output of the National Tube Company and of the independent mills now in operation is sold up to the date mentioned, and the opening up of a few more mills will do no more than relieve the market of the present stringency of Pipe. The market in the metropolitan district is in fair shape; prices are stable and the demand is in good volume. No complaint is heard of cutting in prices among the jobbers. Probably this is due to the fact that the margin of profit is too small to admit of cutting, and, judging from the way the majority of the trade speak, the demand is very satisfactory. It is to be expected, however, that this being very close to the end of the year a number of jobbers will make an earnest effort to reduce the stock now on hand to a minimum before January 1.

Gasoline Fire Pots and Torches.—The Clayton & Lambert Mfg. Company, Detroit, Mich., as recently reported in these columns, have issued new prices on their Gasoline Fire Pots, or, as they are more generally known, Furnaces, and Torches. It is seldom that a change is made in the price of these goods, consequently the trade will be interested in the new lists, which are as follows:

Number.	Fire Pots.	Catalogue or selling price of each.
1.....		\$6.00
5.....		4.50

6.....	4.00
10.....	3.00
20.....	3.25
2.....	20.00
3.....	25.00
4.....	30.00
7.....	6.00
15.....	8.00

Torches.

Number.	Catalogue price, each.	
1.....	Polished brass, \$3.00	Nickel plated, \$3.25
2.....	Polished brass, 2.50	Nickel plated, 2.75
3.....	Polished brass, 2.00	Nickel plated, 2.25
4.....	Polished brass, 2.00	Nickel plated, 2.25
5.....	Polished brass, 3.00	Nickel plated, 3.25
6.....	Polished brass, 3.00	Nickel plated, 3.25
7.....	Polished brass, 2.25	Nickel plated, 2.50
8.....	Polished brass, 2.00	Nickel plated, 2.25
9.....	Polished brass, 2.50	Nickel plated, 2.75
10.....	Polished brass, 1.00	Nickel plated, 1.10
11.....		Nickel plated, .75
12.....		Nickel plated, .75
13.....		Nickel plated, .75
14.....	Polished brass, 1.00	Nickel plated, 1.10
15.....	Polished brass, 2.25	Nickel plated, 2.50
16.....	Polished brass, 2.25	Nickel plated, 2.50
17.....	Polished brass, 2.50	Nickel plated, 2.75
18.....	Polished brass, 2.00	Nickel plated, 2.25
19.....	Polished brass, 2.25	Nickel plated, 2.50
20.....	Plain, 1.50	
21.....		Nickel plated, .50
22.....	Polished brass, .75	Nickel plated, .85
23.....	Polished brass, .75	Nickel plated, .85
24.....	Polished brass, 2.00	Nickel plated, 2.25
25.....	Polished brass, 2.25	Nickel plated, 2.50
26.....	Polished brass, 2.25	Nickel plated, 2.50
27.....	Polished brass, 2.00	Nickel plated, 2.25
28.....	Polished brass, 2.00	Nickel plated, 2.25
29.....	Polished brass, 2.00	Nickel plated, 2.25
30.....	Polished brass, 2.25	Nickel plated, 2.50

Screws.—The market on Screws is in a somewhat unsatisfactory condition, and prices are irregular. Both 87½ per cent. and 90 per cent. are used as base discounts by the manufacturers, but extras are given freely according to the quantity, desirability of order, standing of the customer, &c. There does not appear to be any immediate prospect of an agreement among the manufacturers which will have the effect of advancing prices or of controlling the market.

Tin Cans.—The recent action of the American Can Company in reducing the price of Tin Cans in order to shut off outside competition has been followed by the independent Can makers, practically all of whom have also marked down their price in correspondence with the reduction made by the combination.

Wire Nails.—Some irregularity in the volume of demand, which fluctuates from day to day, is noted in the Wire Nail market. This, however, does not affect the aggregate quantity of Wire Nails going into consumption. Small lots from store are quoted at \$2.35 to \$2.40 per keg.

Cut Nails.—The demand for Cut Nails is confined to moderate proportions, the amount of business being about normal for the season. Small lots from store are quoted at \$2.25 per keg.

Wire.—Former conditions rule in the Plain Wire market. There is considerable unevenness in prices, and in some cases considerable cutting is noted. Small lots of Plain Wire, New York, are quoted at about 2.55 cents, and Galvanized at 2.95 cents.

Window Glass.—The trade is quiet, and lower prices would not be surprising after the first of the year. Reports indicate that the Window Glass manufacturers outside the combine show little disposition to come to an agreement to maintain prices.

Linseed Oil.—The local Linseed Oil market is somewhat unsettled by resales of low priced Oil, which is being offered to the trade at a considerable reduction from ruling prices for Raw. This Oil was contracted for some time ago at low figures. The advance of Flax Seed in the West has had a stiffening effect upon the market generally. Spot business is light, and the uncertainty of the future of the market has deterred buyers from placing contract orders. City Raw Oil in small lots is quoted at 56 to 57 cents per gallon, Boiled Oil being 2 cents advance on Raw.

Spirits Turpentine.—During the early part of the week consumers came into the local market and purchased a quantity of Turpentine. Southern advices report firmness at that point, with a large demand. The market here is strong, moderate sized lots from store being quoted at 39 to 39½ cents per gallon.

TRADE NOTES.

THE ARC LAMP COMPANY of New Jersey, with principal office at 679 Broad street, Newark, N. J., have been incorporated with a capital stock of \$10,000 to manufacture Oil Lamps, &c. The incorporators are: John Dougherty, Allen B. Feehan and Horace L. Smith.

It is said that the new plant of the Columbian Enameling & Stamping Company at Terre Haute, Ind., is regarded as so absolutely fire proof that no insurance will be carried on any of the buildings, except the warehouses and their contents.

THE directors of the Illinois Pure Aluminum Company of Lemont, Ill., have decided to spend \$50,000 during the coming year in improvements in their plant. The company expect to add 15,000 or 20,000 square feet of floor space and to install a number of new machines. This extension is made necessary by the increasing business of the concern.

THE MESTA MACHINE COMPANY, Lewis Block, Pittsburgh, have received an order from the La Belle Iron Works, Steubenville, Ohio, for a Mesta Patent Pickling Machine, to pickle Pipe up to 22 feet in length, and a large Billet Shear to cut up to 4 x 30 inch sections on hot steel. The Shear will weigh about 125 tons and will be driven by an engine.

THE MANHATTAN BRASS COMPANY, 362-368 Avenue A, New York City, suffered a \$10,000 loss by fire December 5.

ADOLPH LEWISOHN has retired from the firm of Lewisoohn Brothers of New York.

THE December issue of *Graphite*, published by the Joseph Dixon Crucible Company, Jersey City, N. J., contains much interesting information relative to the uses to which Graphite is put, and gives a complete list of the numerous productions of the company.

THE directors of the National Enameling & Stamping Company, New York, have declared a dividend of 4 per cent. on the common stock, payable at the rate of 1 per cent. quarterly. The directors also decided to anticipate the redemption bonds of the company, amounting to \$250,000, which mature on September 1, 1902, redeeming them at par with interest.

YOUNG BROTHERS, 320 to 326 Atwater street, Detroit, Mich., will erect during the winter a two-story brick factory building covering a ground space of 95 by 100 feet, and to cost about \$8000. The power is to be a gas engine. The firm do a general jobbing business in Copper and Sheet Iron work, manufacturing Copper Stills, Kettles, Percolators, and special apparatus for manufacturing pharmacists, chemists and for laboratories; also Copper Steam Pipes, Coils, &c., for factories, steamboats, &c. They further manufacture Sheet Steel Smoke Stacks, Breechings, Tanks, and all kinds of special work in that line, and make a specialty of the Cyclone Exhaust Head and Young's Improved Automatic Water Still. It is owing to the increasing sales of these goods that they are enlarging their plant to about six times the size of their present factory. They are equipping the engines of some of the largest plants in the country with the Cyclone Exhaust Head and are running overtime to keep up with orders. Their Water Stills are used in hotels, hospitals, schools and laboratories and are found especially desirable for electric storage battery plants, where nothing but pure water can be used.

THE AMERICAN SHEET STEEL COMPANY have removed their Chicago offices from the eleventh floor of the Marquette Building to a larger suite of rooms on the tenth floor of the same building. The company's Chicago business is not only large, but is constantly increasing, and it was found necessary to secure additional space to accommodate a greater office force.

THE recent addition of \$1,000,000 to the capital stock of the Youngstown Iron Sheet & Tube Company, Youngstown, Ohio, has all been paid in, giving the concern a paid up capital of \$2,000,000. Plans are being

drawn for an Open Hearth Steel plant, work on which will start in a short time.

THE IMPERIAL EXPANDING METAL COMPANY, with principal office at 419 Market street, Camden, N. J., have been incorporated, with a capital stock of \$250,000, to manufacture Expanded Metal, Fire Proofing Materials, &c. Augustus M. Eddy, Charles W. Hills, Anna B. Hills and Louis J. Delson are the incorporators.

In the experiments in electric traction on the Prussian military lines, says the Berlin correspondent of the *London Times*, a speed of 99½ miles an hour has been attained, the force employed being 10,000 volts. It is said that if the lines were strengthened this rate of speed would be quite practicable.

Entered at the Post Office, New York, as Second-class Matter.

LABOR EXCHANGE.

Notices under this heading of reasonable length are inserted free of charge. Only those relating to employment are admitted. Write distinctly on one side of paper only, and do not use postal cards.

Official letters of reference should not be enclosed with replies to advertisements appearing in these columns as they are frequently mislaid and lost. A copy of the reference will serve the purpose.

HELP WANTED.

A good FURNACE MAN can find a permanent paying position in New York City with a future if he is the right kind. I want a man to be my general assistant. He must be able to make his own visiting list in soliciting orders for high grade furnace work and have the address to secure an audience with architects and high class custom trade. He should have a competent knowledge of the business in all its branches and detail. Must be able to go to a building and measure and design the work and then take charge of the men or superintend the job. A man with a knowledge of steam and hot water work and familiar with buying all kinds of heating materials and estimating and ability in the office is the kind of a man I want, if he has ambition. To the right man I offer an opportunity. "Warm Air Man," care *The Metal Worker*, New York. Dec. 14

Bright young men, unmarried, who would like to learn the tin and sheet iron business; steady work; those with some knowledge of the business preferred; steady work and advancement according to ability; young men who would be willing to learn to erect work on the road. Apply to Box 428, Hartford, Conn. Dec. 14

Experienced SALESMAN for our steam and water heaters in Philadelphia and vicinity. The Prize-Painter Stove Heater Company, Reading, Pa. Dec. 14

An experienced SHEET METAL STAMPER for stamping sheet metal ornaments; must be a hustler and able to make his own dies; steady work for the right man; give age, experience and wages expected. Gerock Bros. Mfg. Company, 1252 Manchester avenue, St. Louis, Mo. Dec. 14

To correspond with good all-round TINNERS and PLUMBERS who don't use tobacco; sober and steady; a good, steady job every day; those who take an interest in their work and do it right preferred. Geo. W. Gibney, Pawling, N. Y. Dec. 14

An experienced man to work on power press to form cornice molding; must understand his business. "Energetic," care *The Metal Worker*, New York. Dec. 14

A situation is open for a first-class MOLDER; about 40 years of age; competent to act as assistant foreman in foundry making ranges, furnaces and hot water or steam boilers; state wages expected, and give references. "Range," care *The Metal Worker*, New York. Dec. 14

A practical FOREMAN; must be competent to figure and give estimates on furnace and all kinds of house heating, all kinds of plumbing and sheet metal work; shop employs from 15 to 20 men; good salary and interest in the profits to a competent and industrious man; must be a total abstainer; send references. "Letter Carrier, No. 97," Brockton, Mass. Dec. 14

EXPERIENCED SALESMAN for New England trade. Phillips & Clark Stove Company, Geneva, N. Y. Dec. 14

SUPERINTENDENT OF FOUNDRY, understanding thoroughly the molding, pattern and mounting business pertaining to the manufacture of stoves, ranges, furnaces and house heating boilers; New England man preferred; state experience, where now employed, salary expected, and how soon could leave present position; good opportunity for advancement. "H. D. J.," care *The Metal Worker*, New York. Dec. 7

GALVANIZING FOREMAN wanted who can construct and manage small plant. "Confidential," care *The Metal Worker*, 117-119 South Fourth street, Philadelphia, Pa. Dec. 7

At once, a first-class TINSMITH who understands furnace and bench work and general jobbing in country town 40 miles from New York; a yearly job at good wages; must be steady and sober. "Yearly," care *The Metal Worker*, New York. Dec. 7

By a manufacturer of gas ranges, a man to fill the position of INSPECTOR; must understand thoroughly the requirements of the position; kindly give experience and salary wanted; a permanent position to the right man. "Gas Range Manufacturer," care *The Metal Worker*, New York. Dec. 7

For 1902, a first-class SALESMAN with an acquaintance with trade in New York and adjacent territory; references; state salary expected, age and experience. "Experienced Man," care *The Metal Worker*, New York. Dec. 7

SPINNER for sheet metal; must be first-class; highest wages. Apply to the Pedlar Metal Roofing Company, Oshawa, Canada. Dec. 7

Immediately, two good SLATE ROOFERS. Apply to the Peet & Schuster Company, Springfield, Ohio. Dec. 7

Young man about 20 to 25 with experience on roof and furnace work, in a regular jobbing shop; must be a hustler; German preferred; state wages; a steady job to the right man. William Pahland, 415 Richmond Terrace, New Brighton, S. I., N. Y. Dec. 7

Two first-class TINNERS and SHEET IRON WORKERS; must be sober and strictly business-like. A. J. Shide, 103 South Forsyth street, Atlanta, Ga. Dec. 7

At once, an up to date TRAVELING MAN who can show a good selling record; one that has an acquaintance among the hardware and implement trade in Iowa preferred and capable of selling a varied line to the above class of trade. Address Lock Box 712, Des Moines, Iowa. Dec. 7

A HOUSE HEATING BOILER SALESMAN of experience, with A1 reference; must be of good character and habits; give full particulars, with salary expected. "Character," care *The Metal Worker*, New York. Dec. 7

At once, a good, sober, competent TINNER, PLUMBER and FURNACEMAN for inside and outside work; steady job for the right man; state wages expected and give references; good college town. N. B. Twogood, Mount Vernon, Iowa. Dec. 7

SUPERINTENDENT for a stove and range manufacturing business; one who is thoroughly familiar with the construction of stoves and steel ranges, also must have some experience in nickel room; references required; young man preferred. "W. H.," care *The Metal Worker*, New York. Dec. 7

January 1, 1902, a first-class TINNER at inside and outside work, hot air furnace, steam and hot water, some plumbing and wind mill work; wages \$12 per week; steady work the year round; must be honest, sober and industrious, with some knowledge of hardware; give references. Box 177, care *The Metal Worker*, 1205 Fisher Building, Chicago, Ill. Dec. 7

A good TINNER, understanding all the branches, also furnace work and plumbing, thoroughly; young man of good habits preferred; steady work. "D. P. B.," Forestville, N. Y. Dec. 7

A bright, hustling salesman, fully experienced in the plumbing supply business; a fine opportunity for the right man. "B. G.," care *The Metal Worker*, New York. Nov. 30

FOUNDRY SUPERINTENDENT who is capable of taking entire charge of a large stove plant; state experience, reference, age, &c. "Trade-Mark," care *The Metal Worker*, New York. Nov. 23

First-class SALESMAN to travel and sell a large line of stoves, ranges and furnaces in the New England States; one who can sell goods may address, with references. "W. H. G.," care *The Metal Worker*, 70 Kilby street, Boston, Mass. Nov. 23

SITUATIONS WANTED.

TIN and SHEET IRON WORKER understanding stove and range work; 18 years of experience. "Finer," 522 Tenth avenue, New York. Dec. 14

Expert HEATING ENGINEER; skilled draftsman, designer; thoroughly practical in the mechanical and commercial parts of the heating business, would engage with some manufacturer making, or soon to make, a full line of heating boilers who is a pusher for business; references furnished. "Expert," care *The Metal Worker*, New York. Dec. 14

A PLUMBER wishes work in city or country; ten years' experience. Address Thomas M. Spedon, 328 East Sixtieth street, New York. Dec. 14

By a practical PLUMBER and STEAM FITTER with 15 years' experience, sober and reliable, can estimate from plans and will guarantee to be a first-class lead worker, also capable of figuring radiation, a hustler and up to date; desires to make a change to some Southern town or city where the winters are not severe; correspondence desired for steady position only. John Recter, General Delivery, Glens Falls, N. Y. Dec. 14

By a first-class PLUMBER, GAS and STEAM FITTER with 12 years' experience; a first-class lead worker and capable of doing all kinds of steam and hot water heating; strictly temperate in habits; can take charge of work if necessary; all I ask is a fair trial,

but do not care to correspond with any but reliable firms that can give steady employment if satisfactory. "Practical," 90 West street, Glens Falls, N. Y. Dec. 14

By an A1 mechanic; can make anything that can be made out of sheet metal, and cut patterns for same; 22 years' experience. "X.," 1104 Russell street, Detroit, Mich. Dec. 14

An ENGINEER with good business qualifications and practical experience with all kinds of house heating and plumbing systems, would make a change from present position; competent to act as manager, engineer or buyer in connection with either a heating or plumbing business; good draftsman; good references; would go South or West; well acquainted with New England trade. Address "H. & P.," care *The Metal Worker*, 70 Kilby street, Boston, Mass. Dec. 14

By TRAVELING SALESMAN, for 1902, position with an established trade in tin plate and sheet metals in Ohio, Indiana; nothing less than \$2000 a year salary and expenses will be considered. Address Lock Box 56, care Station A, Columbus, Ohio. Dec. 14

Young man, age 27, experienced bookkeeper, with four years' experience in the retail hardware business, desires a position with a good wholesale house. For references and particulars address Lock Box 21, Wayland, N. Y. Dec. 14

Young man, age 25, wants good line of goods, stoves or hardware, for Western Pennsylvania and Ohio; acquainted with trade and best of references. "V. A.," care Anderson Hotel, Bellaire, Ohio. Dec. 14

By a PLUMBER, 24, eight years' experience; temperate and steady; would like to work in tin shop where I could learn tinsmith trade. "Plumber," care *The Metal Worker*, New York. Dec. 14

As TRAVELING SALESMAN or MANAGER of hardware store; 14 years' experience in the retail trade; seven years on the road for stoves in Eastern New York and New England. "Experience," care *The Metal Worker*, New York. Dec. 14

By a practical experienced stove moulder and pattern fitter as FOREMAN; have the ability to manage men with satisfaction; would like to correspond with some stove firm. "F.," care *The Metal Worker*, New York. Dec. 14

By a CORNICE MAKER of 14 years' experience; understands cutting; no objection to bench work; Southern States preferred. "J. S.," care *The Metal Worker*, 117-119 South Fourth street, Philadelphia, Pa. Dec. 14

Young man, 18, wishes to begin as learner in any branch of the metal trade; no previous experience; willing to work. Mack Lascher, 126 Boerum street, Brooklyn, N. Y. Dec. 14

BOOKKEEPER, age 30, single; thoroughly experienced in manufacturing line; up to date methods; all round man; capable of taking charge of office; exceptional references; salary desired, \$20 per week. "Broad," care *The Metal Worker*, New York. Dec. 14

By a young man, age 28, at present employed by large range, stove and heater concern; experienced in bookkeeping, cost accounting, correspondence and shipping. "E. A. C.," care *The Metal Worker*, New York. Dec. 14

A man fully acquainted with all the details of the wholesale plumbing and steam supply trade, desires permanent engagement; references exchanged. "Capable," care *The Metal Worker*, New York. Dec. 14

Of trust by a master PLUMBER and HEATING MAN of 30 years' experience, 15 years as traveling salesman selling to the trade; can make plans; good solicitor, and superintend work; A1 testimonials; up to date with acetylene plants. "M. J.," Box 700, Milford, N. H. Dec. 14

A first-class, practical DESIGNER wishes to change his position; expert in designing ornament; proficient in all the styles; is a capable wood carver and for the past five years has been the designer for a large pattern shop making a specialty of high-class stove patterns; has good business training and executive ability; makes perspective water color sketches and details; can submit samples and photos; possesses highest references and is willing to invest some capital in a good proposition. "Steel," care *The Metal Worker*, New York. Dec. 7

By a young man in the sheet iron manufacturing line as BUYER or ASSISTANT; has had office and factory experience and is familiar with cost and estimate work on special sheet iron goods. "Iron," care *The Metal Worker*, New York. Dec. 7

To represent manufacturers as their agents on the Pacific Coast, strictly on commission, the following lines: Steel ranges, up to date air tight heaters, steel and cast hollow ware, stove pipe, elbows, dampers, rods, bolts, urns or kindred lines. What have you got? "S. A. M.," 748 First street, Portland, Ore. Nov. 23

MFG & CO.
NICKEL-STEEL WARE

Patented Feb. 12, 1895.

COST	SELL
<p>Analysts No. 72,830. New York, Dec. 7, 1894. We have made a careful examination of a sample of "Agate Nickel Steel Ware" received from The Lalance & Grosjean Mfg. Co., Nov. 30, 1894. The enamel coating is homogeneous, of extra thickness, and great purity. It is entirely free from arsenic, lead and anti-mony—metals so often found in enameled goods. Very respectfully, STILLWELL & GLADDING, Chemists to the New York Produce Exchange.</p> <p>{ Pierre de P. Ricketts, E.M., Ph.D. { John H. Banks, E.M., Ph.D. Analysts No. 14,120. New York, May 6, 1897. LALANCE & GROSJEAN MFG. CO. GENTLEMEN—As requested by you, we purchased in the open market a sample of "Agate Nickel Steel Ware" and have made a careful chemical analysis of the enamel covering of the same. We find this enamel is absolutely pure and free from Arsenic, Antimony, Lead and other substances injurious to health. We can therefore recommend it for all culinary and drinking purposes. Respectfully yours, RICKETTS & BANKS, Chemists to the N. Y. Metal Exchange. Guaranteed Double Coated and Absolutely Pure Copyrighted.</p>	

Read carefully the Chemists' Certificates.

Send for pamphlet soon to be issued. **Lalance & Grosjean Mfg. Co.**

Domestic Electrical Work.

Concise and Practical Explanations for
Plumbers, Tinnerns and Hardware Dealers
on How to Wire Buildings for Bells,
Alarms, Annunciators, and for Gas Light-
ing from Batteries.

Illustrated with Twenty-two Diagrams.

By **WILLIAM A. WITTBECKER**

Price in Paper, 25 Cents.

Price in Cloth, 50 Cents.

The growing demand for simple electrical apparatus in dwelling houses, offices and workshops, and the need of plain instructions whereby any person without a previous knowledge of electricity may be enabled to undertake their successful installation, has prompted the publication of this little book. It is not intended for the amateur who seeks for nothing but experimental work, neither is it expected to enlighten the expert electrician; but to the person who is seeking for information that will assist him in increasing his daily earnings this little volume is addressed. The information given is above all else practical and with a close observance of the directions laid down any one without the slightest knowledge of electricity should be able to do the work described.

CONTENTS.

- Chapter I.—Simple Bell Circuit.
- Chapter II.—Multiple Bell Circuit.
- Chapter III.—Various Circuits.
- Chapter IV.—Fire Alarms.
- Chapter V.—Annunciators and Alarms.
- Chapter VI.—Burglar Alarms.
- Chapter VII.—Automatic Fire Alarms.
- Chapter VIII.—Electric Gas Lighting.
- Chapter IX.—Running Wires in Finished Buildings.

A UNIVERSAL
REMEDY FOR

LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 600 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails. In 5, 10 and 15 lb. Pails.

Special Discount to Jobbers and Large Buyers.

MANUFACTURED BY

WILLIAM CONNORS PAINT MFG. CO., - Troy, N. Y.

For TINNERS, SLATERS, ROOFERS and BUILDERS.

Galvanizing and Tinning.

A Practical Treatise on Coating with Tin and Zinc, with a Special Chapter on Tinning Gray Iron Castings. By W. T. Flanders. Size 5½ x 8 inches. 98 pages, 40 illustrations. Cloth bound. Price \$2.00.

The author of this work has made a specialty of galvanizing and tinning, and has been employed to erect plants in various parts of the country, also to instruct the owners, so that, in all instances, they have been able to operate them successfully. The subject of galvanizing is, therefore, treated from the standpoint of an expert and in a practical manner. The selection of materials and apparatus for erecting plants of large and small capacity is treated, together with instructions for their equipment and accompanied by many illustrations of the plants and of the tools and appliances. Plain directions are given for the preparatory treatment of metals and articles to be coated, and every detail which is of importance in successfully applying to metals a secure and attractive coating is described. The tinning of articles is treated in the same practical manner. The difficulties found by many who have attempted to tin malleable and gray iron castings are explained and methods for doing the work made simple.

CONTENTS.

Galvanizing.

Locating a Plant and Selecting a Kettle.
The Galvanizing Room.
Tanks for Acids and Other Purposes.
Tools for Galvanizing.
Filling and Firing a New Kettle.
The Use of a Pyrometer.
Materials Used in Galvanizing.
Building and Setting Kettles.
Removing Scale with Sulphuric Acid.
Cleaning Sandy Castings with Sulphuric Acid.
Preparing the Work for Dipping in the Zinc Bath.
Drying the Work.
The Heat of Zinc.
Dipping the Work in the Molten Metal.
The Formation of Dross in the Kettle.
Running Over, or "Sweating," Zinc Dross.

Tinning Malleable Iron, Wrought Iron and Steel.

Preparing the Work.

ART
IN
Metal Ceilings
GOTHIC STYLE.

One of the noblest styles of architecture and design is that known as Gothic.

The round arch style originated in France, the pointed arch being a later development.

From France, Gothic was introduced in England and Germany. It became extremely popular for churches, and is, perhaps, the leading one of the accepted styles for that purpose.

For the interior decoration of churches our Gothic design is particularly appropriate. The background is supplied with stucco effect. The ornamentation is elegant in simplicity and thoroughly in harmony with the characteristics of this historic style.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting
as applied to all branches
of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection
of 218 problems and an elaborate
explanation of the principles of
pattern cutting, including Triangu-
lation.

It embodies the problems of the
former Metal Worker Pattern Book,
all of which have been revised, and
many of which have been entirely
rewritten and solved by more ap-
proved methods. To these have
been added 75 new problems and
much other new material and ex-
planatory matter, making this work
a model of completeness in every
respect.

ARRANGEMENT.

In point of arrangement the new
work far surpasses the former one
in that the problems are classified
under three different heads, and
simply indexed, and also that by
means of a table of contents any
required department of the work
can be easily found.

CONTENTS.

While Chapter VI, comprising the
greater part of the work, is devoted
to the solution of problems, the
five preceding chapters thoroughly
explain the principles of pattern
cutting, and place the student in
possession of the preliminary infor-
mation necessary to a thorough
understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tanners, Cornice Makers and
Sheet Metal Workers should be
provided with a copy of

THE ELECTRIC CITY GUTTER FORMER.

The Electric City Gutter Former can be bought for 50 per cent. less than other machines intended for the same purpose. This machine will do everything that can be accomplished by any other gutter former. No other machine can do better work. No other machine can do quicker work. The principle of this machine is entirely different from any other. It is more practical. Both the head and the gutter are formed in one continuous operation. You do not waste any time in hard work in getting the body of the gutter in proper shape. Every operation is mechanical. Each length of gutter is formed exactly alike. No other machine is as practical in its operation. No other machine will give as much satisfaction. The low price is very attractive. The machine will perfectly demonstrate our claims. Ask us about it. We gladly furnish information and price on request.

THE DOUBLE TRUSS CORNICE BRAKE CO., - 1453 Niagara St., BUFFALO, N. Y.

Our Improved Double Truss Cornice Brake is the most practical machine of its kind in the market. Let us send you a description of its merits. Our "latest" has a double edge on front leaf for making fine members and corrugations.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No. 12 gauge, cut wire or bar-steel ½ inch thick, cut off and mitre angle iron ½ inch thick, and do it perfectly.

The **BOYNTON FURNACE CO.,**
NEW YORK, CHICAGO.

Do You Keep Right Company?

People are frequently judged by the company they keep. A heating contractor is apt to be judged by the heaters he keeps company with.

If he handles a heater that the consumer has learned to look upon as best, his ability as a fitter will likely be considered *Al*. Of course this isn't always true, but in the majority of cases it is. It's natural for people to think that if a dealer carries better goods he'll do that kind of work—they'll have more confidence in him.

The name "Magee" as connected with heating apparatus, has been favorably known for nearly a half century—has always stood for highest quality, as it does now. It certainly does help to turn patronage to contractors who use Magee Heaters. This is not idle talk. Fitters frequently write that the name "Magee" in their bids has helped them land this or that contract, even when their bids were highest.

MAGEE FURNACE CO., 32-38 Union St., Boston.

Makers, also, of the celebrated Magee Ranges and Furnaces.

Gold Medal, Highest Award, Paris Exposition.

Magee
HEATERS

FOR STEAM AND HOT WATER

Capacities: 100 to 6900 square feet Water Radiation; 200 to 4200 square feet Steam Radiation.

Most complete line made under one name in the United States.

Are you among those who have found MAGEE HEATERS profitable company?

QUICK MEAL

GASOLINE STOVES.

THREE important qualifications have brought about the "Quick Meal's" immense and ever increasing sale—Name, Quality and Merit.

The Name "Quick Meal" is well known and respected everywhere. The name "Quick Meal" on a stove is a strong guarantee in itself; it has for twenty years stood for "Recognized Standard of Excellence."

The Quality has always been the highest. The materials used are the very best that can be bought, and the workmanship is perfect owing to an intelligent force of skilled mechanics aided by long experience and an equipment of the best tools and machinery that money and brains can assemble. Merit has brought the "Quick Meal" to the front and keeps it there. It is perfect in its operation and it has always fully met every requirement. The name "Quick Meal" and its high quality of material and workmanship sell the stove; its perfect action when in use keeps it sold and sells more.

RINGEN STOVE CO.

SAINT LOUIS

1902

RELIABLE VAPOR STOVES

AND RANGES.

It is a source of gratification that we are again able to point to a number of improvements for the coming season, that not only signify our desire to keep abreast of the times, but our determination to keep the RELIABLE in the position it has so long enjoyed, that places it beyond competition.

Our trade-mark "RELIABLE" stands for all that is best in stoves the world over. If you wish to control the vapor stove business of your city, place a sample line of RELIABLE stoves on your floor. They will do the rest. This is the line that never disappoints.

Send for 1902 Vapor Stove Catalogue. It is yours for the asking.

Monarch Vapor Stoves.
Monarch Blue-Flame Oil Stoves.
Monarch Asbestos-Lined Ovens.

THERE has always been a **Striking Individuality** about Monarch Goods, and for the coming campaign we have very greatly increased this **important feature** by incorporating in **every pattern**, from the most **complete Family Range** to the cheapest **low Junior**, a number of **special features** entirely **original** with ourselves, so that **Monarch Agents** will be **greatly profited** in pushing **Monarch** goods exclusively. Our **NEW CATALOG** is going to be the **most beautiful edition** ever issued. Will be ready by January 1st. We are pleased to inform the trade that we will be represented in your territory by the branches and agents mentioned at foot, who will look after your interests very carefully, and serve you in the best manner possible. All correspondence coming from their territory will be forwarded to them promptly and receive the same prompt attention from the factory. We promise you the **BEST SELLERS** on the market, and only ask a **chance** to show you samples. **Monarch** goods do their own talking, and are "Bread cast upon the Waters." Drop us (our Branches or Agents) a postal for a copy of the **NEW CATALOG**. **IT WILL PAY.**

WINCHESTER

How often success in man or goods is ascribed to "luck." We all know better. Intelligence, ability, diligence and merit make for success and not for failure. Do you suppose the "WINCHESTER" steam or water heater would have proved the success it has if it were merely "lucky"? Made by Smith & Thayer Co., Boston, Mass.

HEATER.

IN a large store on Washington St., Boston, they had a strong, well made boy's Express Wagon that *they* retailed with the maker's *name* at \$4.50.

In another large store (the block below), was exactly the same wagon, same size, weight, material, finish and built by the same maker, but without the maker's name on it, and the retail price was \$3.50.

The one without the maker's name has been used for the last two months by four good, healthy youngsters, ranging from five to eleven years old and is apparently in as good condition as when new.

You don't believe the maker's name could have made the other one of any more real value in any way?

We would like to impress upon you the fact that not one single penny of the price you pay for a "DIGHTON" Furnace is for a name. The "DIGHTON" price is for real furnace value, the real worth of the article, what it will do and the results your customer secures with it as compared with what some other Furnace has done under the same conditions.

DIGHTON FURNACE CO.,

The Stanton Seamless Heater,

PORTABLE CASED.

LOUISVILLE, Ky., Apl. 5th, 1901.

THE STANTON HEATER CO.,
 Martin's Ferry, Ohio.

Gentlemen:—Your favor of the 3d inst. is received asking our experience with the Stanton Heater which you put in for us during the fall of 1899. In reply we will say that it gives us pleasure to express our entire satisfaction with this Furnace. While we have had no severe weather this winter there have been several quite cold snaps, but our offices have been very comfortably heated, and our coal bill (Pittsburgh coal) has been quite moderate compared with other Heaters we have used.

The satisfaction the Heater has given us can be best expressed by saying that we have not heard the Furnace mentioned once this winter. You can see, therefore, that we have had absolutely no cause for complaint.

Yours very truly

The Climax

RATCHET STOCK

Is an indispensable tool for conveniently threading iron pipe in ditches, under floors, in corners, over head, etc. With this tool threads can be cut without removing whole lengths of pipe. This tool is provided with a strong vise which securely grips the pipe and by means of the leading thread the die is forced on pipe and the thread is cut. It is made of malleable iron and steel, and while light in weight, making it convenient to carry, is very strong and rigid. The advantages of this tool make it absolutely indispensable to Plumbers, Steam and Gas Pipe Fitters, Gas and Water Companies, Machinists, etc. It takes standard size dies, which are extra if furnished.

No. 1 threads ¼ to 1 in. pipe, takes 2 or 2½ in. die, \$10.00.

No. 2 threads 1 to 2 in. pipe, takes 2½, 3 and 4 in. die, \$17.00.

For sale by leading jobbers.

Practical Hints

on Joint Wiping,

For Beginners in Plumbing.

SIXTH EDITION, ENLARGED.

With an Appendix Giving a Selection of Practical Letters and Articles Compiled from THE METAL WORKER.

16 Pages. 41 Illustrations. Paper, 25 Cents.

This edition contains besides the two original articles on joint wiping, by experts, a selection of letters and articles on various important phases of the subject. These include the following:

- Joint Wiping on Copper Pipe.
- Wipe Joints on Brass and Iron.
- Wiping Joints on Tin Pipe.
- Wipe Joint on Lead and Iron Pipe.
- To Make Tight Joints.
- Froze the Pipe to Wipe a Joint.
- Wiping Joints Without a Furnace.
- The Effect of a Jar on a Hot Wiped Joint.
- What Caused the Joint to Break?
- Strength of Joints in Lead Pipe
- Good Wiping Solder.
- Durability of Coarse Solder.
- Plumbers' Paste.
- Cleaning Solder.
- What Breaks Wiped Joints?
- Hard Solder to Resist Ammonia.

The first article in the book is written by a practical plumber, and is illustrated from photographs representing the hands and tools when wiping joints in various positions. The second, by an expert joint wiper, is also illustrated from photographs and will prove of great assistance to learners. Ample instructions are given on preparing the pipes previous to wiping the joints, with full descriptions of all tools and appliances used. The pamphlet, in short, gives all the assistance that description of the work can furnish and is the most practical and complete account of joint wiping that is published.

A Step in the Right Direction.

The conference of prominent capitalists and labor leaders and others interested in the industrial question, held this week in New York City, under the auspices of the National Civic Federation, has resulted in a step which should be of far reaching importance. After two days of frank and admirably tolerant discussion of the relations between labor and capital, it was decided to appoint a committee of 36 members, representing, in equal numbers, the employers, the workmen and the general public. The *personnel* of this committee should secure for it the confidence of the public at large. Among its members are men who are widely known and respected in their different spheres. The chairman is Senator Marcus A. Hanna, and the vice-chairmen Oscar S. Straus, former Minister to Turkey, and President Samuel Gompers of the American Federation of Labor, and among the members are such men as ex-President Cleveland, Archbishop Ireland, Bishop Potter, President Eliot of Harvard, President Mitchell of the United Mine Workers, Grand Master Sargent of the Brotherhood of Locomotive Firemen; T. J. Shaffer, president of the Amalgamated Association of Iron, Steel and Tin Workers; Martin Fox, president of the National Iron Molders' Union; James O'Connell, president of the International Association of Machinists, and several other prominent labor leaders, with President Schwab of the United States Steel Corporation, S. R. Callaway of the American Locomotive Works; Charles A. Moore, president of the National Tool Company; William H. Pfahler of the Abram Cox Stove Company, Philadelphia, and other leading representatives of large employing corporations, representing capital. The committee, as formed, represents a very high standard of character and intelligence. The very fact of such a committee, which is designed to be practically a court of arbitration and conciliation, having been made possible is one of the most hopeful developments of modern times. While it is too much to expect that this step insures the introduction of an era of general industrial peace, it is without doubt a substantial step toward that end. It is assuredly a laudable attempt to do away with the industrial wars which have caused so much loss and suffering in the past. It is, moreover, a recognition of the fact that the interests of capital and labor are mutual, and that one cannot suffer serious injury without the other also being hurt. A most encouraging sign of growing betterment in the relations between capital and labor in this country was

the admirable spirit displayed in the discussions of the conference. There was manifest throughout a spirit of mutual forbearance and an evident desire to come to an understanding for the benefit of all which is highly gratifying and which promises much for the success of this latest effort toward industrial peace.

Splendid Gifts to Education.

The announcement of great gifts for charitable and educational purposes has become so common an occurrence in this fortunate country that something out of the ordinary in this line is now required to produce anything beyond a passing ripple of interest in the minds of the public at large. The report, published a few days ago, of the bestowal by Mrs. Stanford on the Leland Stanford, Jr., University of California of property valued at \$30,000,000, coupled with the further announcement of the offer of Andrew Carnegie to furnish a sum of \$10,000,000 for the establishment of an advanced educational institution at Washington, were sufficiently striking to attract intense interest and admiration. Mrs. Stanford's magnificent gift is probably the largest benefaction ever received at one time by any educational institution in the world. It is certainly the largest amount ever bestowed by a single individual. Moreover, this gift will appreciate in value as time goes on, as it consists largely of great tracts of land, much of which is still unimproved. Mr. Carnegie's gift is the latest and greatest of a long series of princely benefactions that have flowed from his hand into educational channels in the United States and Great Britain. While official details of this project are not yet made public, it is understood that Mr. Carnegie contemplates the establishment in the national capital of an institution of higher learning, to which graduates of existing colleges and scientific men will be admitted for further study and research, the Government co-operating by giving the students free access to the valuable materials contained in the various departmental buildings and public institutions of the capital. Thus the proposed new college would not rival, but supplement, the existing seats of learning. There appears to be ample room for an institution of this character, and its conception gives another proof of the far seeing sagacity with which Mr. Carnegie is employing his wealth for the benefit of mankind.

Higher Commercial Education.

The laying of the corner stone of the new High School of Commerce in New York City, last Saturday, is worthy of special notice, for it marks a distinctly new departure in connection with the public school system of the country. The necessity for a school of commerce, in which would be given the best and most advanced instruction in everything to help fit young men for a modern commercial career, has for some time been recognized by the business men of New York. Early last year the New York Chamber of Commerce, in connection with the authorities of Columbia University, formulated a plan for the creation of an institution of this kind, which, it is expected, will be developed in the building now being erected under the direction of the city Board of Educa-

tion. This body has heartily co-operated with the originators of the plan, and the new school is designed to be a branch of the public school system of the city. The liberality of the members of the Chamber of Commerce in providing a sum of \$500,000 has made possible the establishment of this school, which undoubtedly fills a recognized need. The rapid advance made by the United States in the past few years to the forefront of the world's commercial nations has created a call for a more highly trained class of young men, capable of coping with the complex requirements of modern business. The first city of the western hemisphere, and the second greatest in the world, is obviously the most fitting place in which a movement for the satisfying of this need should first take form. New York is to be congratulated upon showing herself to be abreast of the times in her educational facilities, and upon the further fact that the public sentiment of her citizens is becoming more and more sensible of the pressing educational needs of the young men now growing up within her borders. The establishment of the New York High School of Commerce is an event of significance to the commercial future of the entire country.

Dust from Heating Apparatus.

It has been the custom of men engaged in other lines of heating to refer to the hot air furnace system of heating as being especially dirty. This, however, is a practice only followed by those in the trade who look out for their own interests alone, and is seldom used by men of broader judgment, who recognize that all indirect systems of heating are likely to be the means of distributing more or less dust through a building. In order to avoid the dust that is necessarily gathered in with the fresh air supply, when it is taken from near the ground, the air supply is often taken at some distance above the ground. Frequently the supply for hot air furnaces is introduced through a duct which extends from 6 to 10 feet above the ground, covered by a hood and having an opening protected by means of wire screens against the entrance of birds, leaves and other foreign matter. In other instances, particularly in large cities, the fresh air supply for a heating system is taken from the roof level through a flue, that in appearance resembles in every way a chimney. This is quite a common custom when a fan system is used to force a large quantity of air through the system of warm air supply ducts. Failure to pay attention to the source of the air supply has brought some trouble to the custodians of the city hall at Atlantic City, N. J., where a blower system is in use. Apparently, there has been no complaint about the heating, but it is said that the hot air flues carry such volumes of dust into the different apartments that in an incredibly short space of time names can be written in the dust that settles on the furniture. The fresh air for the heating plant is drawn in from the police court yard, and the complaint of the dust that comes in with it will doubtless lead to some method of avoiding the annoyance.

Clean Air Supply.

Those who live in the East, where hard coal is quite generally used, and where there is a natural moisture in the atmosphere, do not have the same cause for complaint that is felt in some other sections regarding the dust that follows the use of any indirect system of heating. In many instances, however, those who have moved into sections where the air is not so clean make demands upon the heating contractor for some method of getting rid of the dust nuisance. As a result, heating men have perfected elaborate systems for washing the air by sprays of water and passing it through screens of

cheese cloth in order to arrest the dust. This can be done without difficulty where the attendant expense is not an objection. Those who use hot air furnaces, which bring into buildings large quantities of air, naturally look to furnacemen to furnish some device for checking the entrance of the dust which the fresh air naturally carries with it. In many cases the cold air supply ducts are equipped with frames to which cheese cloth is fastened, and the result is in every way satisfactory when the screens are sufficiently large not to hinder the air flow and the cloths are removed and cleansed with sufficient frequency. In some places it is found that in dry weather the cheese cloth requires changing not less than once in forty-eight hours, while in rainy weather the cloth may last for several days. When the cheese cloth screen is used in a cold air supply the heating is not infrequently hindered, owing to the fact that the meshes soon become filled with dust which prevents the free entrance of air to the furnace. Where a screen is used, the frame work, instead of being just large enough to enter the supply duct at the smallest cross section, in the same way as the damper, should be inserted into the duct diagonally, one of its dimensions being the depth of the cold air supply, with the other as many times the width as can conveniently be inserted. This method gives a larger surface of cheese cloth, and affords a better opportunity for air to enter the duct, while it enables it to continue its usefulness for a long period of time before it is clogged with dust. If those who furnish such filtering screens desire to avoid trouble, they must impress those who require them with the fact that the screens require a great amount of care, and that attention must be given to them frequently and regularly; otherwise the efficiency of the heating apparatus will be impaired. There is ample room for profit to be made from the sale of air filtering devices in connection with indirect heating systems, provided they are arranged in a common sense way, and the owners are made to thoroughly understand that frequent attention is the price of clean, fresh air.

Editorial Notes.

One of the noticeable results of the changed conditions which have characterized the market for the past year or two has been the almost complete elimination of the broker. The consolidation of manufacturing interests has had much to do with this. In former periods the broker frequently drove a thriving business by playing off one manufacturer against another, but of late, owing in part to the influence referred to and in part to the activity of business which has enabled manufacturers to market their goods without his aid, there has been comparatively little opportunity for his operations. The time, however, is apparently not far off when in almost every line competition will be as active as ever, and if there should also be a lessening of the demand, so that orders are eagerly sought after, there is little doubt that any means by which the merchants and manufacturers are brought closer together will be again in favor.

The value to a manufacturer of a reputation for the quality of his product finds many illustrations in the trade. It tends greatly to diminish the expense of marketing goods and serves as a safeguard against fluctuations in demand and price, which carry with them so many attendant uncertainties. A striking example of this is found in the case of a certain manufacturer of one item of hardware, who has no agents or salesmen, who never solicits business, and who asks nearly twice as much for his goods as any manufacturer of a similar appearing article. With this condi-

tion of things, and in spite of his lack of live, up to date business methods, his factory runs full all the time, thus illustrating the inherent strength of a good article, well made, well introduced and whose quality has never been allowed to deteriorate. To acquire such a position for their products is an ambition justifying painstaking and persistent efforts on the part of manufacturers.

THE PLUMBING SITUATION.

Since the Executive Committee of the National Association of Master Plumbers saw fit to abrogate the New York Conference Resolutions it is evident that arbitrary action on the part of many of the members and some local associations is to supplant the arbitration and conciliatory features of that agreement. Already the supply trade in different sections are receiving from some of the associations lists of their members, with the intimation that the sale of plumbing goods to others than these members will be considered a sufficient violation of the trade protection principle to warrant a withdrawal of their patronage. This is a step backward to the "sell to members only" resolution of the New Orleans convention, which caused the most serious difficulty in the plumbing trade in recent years. It is possible that this action is only made to influence the establishment of more satisfactory relations between the sellers and buyers of plumbing goods. We have been informed that consideration has already been given to the subject by the plumbers with this end in view. There is little room for doubt that the manufacturers will be willing to agree to anything that is reasonable so as to prevent any break that would interfere with trade.

John Martin, a former member of the London County Council, in an address recently delivered in New York, expressed the opinion that the Health Department of the city was poorly administered, and attributed the late epidemic of smallpox to this cause. He said: "There are in New York no special provisions for maintaining the personal cleanliness of the people, such as is possessed by every modern city of Europe. Take London, for instance. London is a poorer city than New York. Expenditures there are much less lavish than here. Yet it has no less than 37 great public baths open and four others under construction. London has spent \$6,375,000 on these baths. Disease germs are even more democratic than the American Constitution, and at present there are no facilities by which the people of the poorer districts can have the necessities of a cleanly life. There is now one public bath in Rivington street; but during the term of the next administration many more should be built."

"Progressive prosperity" is a term that well fits the condition of the State of Kansas in the past few years. The latest report of the Kansas State Agricultural Bureau shows that the present has been the best year that the farmers of Kansas have ever known. In spite of the partial failure of the corn crop, the aggregate value of farm products and live stock in the State in 1901 was no less than \$348,292,384, or \$17,000,000 more than last year, and \$45,000,000 greater than two years ago. The season's wheat crop is reckoned at 90,000,000 bushels, which is much larger than any previous wheat crop. While the corn crop was considerably smaller than the average, the falling off in amount was largely counterbalanced by the increase in market value. Corn is now worth about 50 cents a bushel on the farm.

Pittsburgh, by reason of its great number of blast furnaces, rolling mills and steel works, is the largest consumer of fire brick of any city in the world. Four counties of Pennsylvania produce the greatest part of the fire brick used, these being Clearfield, Cambria, Clarion and Clinton counties.

WESTERN STOVE PRICES ADVANCED.

The Western Association of Stove Manufacturers held a very important meeting in Chicago on Tuesday and Wednesday of the present week. The attendance on this occasion demonstrated the interest and enthusiasm of the members, as it is believed that every stove company belonging to the association was represented. The members interchanged views relative to the condition of affairs in the trade, and a sentiment speedily developed in favor of making an advance in prices to conform to the increased cost in the production of goods. It was therefore decided to take steps in this direction. The various manufacturers will immediately withdraw all prices outstanding on stoves and ranges, and it is understood that the new prices to be made will show quite an advance. This association usually takes the initiative in matters of this kind, as it covers a larger area and includes in its membership a greater part of the stove producing capacity of the country than any other of the local associations. It is therefore believed that the example thus set will be followed by manufacturers in other parts of the country.

A SALESMAN ON THE EASTERN STOVE SITUATION.

BY ITINERANT.

I was much surprised in reading over the correspondence about the stove association and their prices, &c., that the poor salesman was not flayed alive for all the shortcomings of the trade. He is the one that has generally been pitched upon for making all the mischief in it, and if he was eliminated and was told to "Go 'way back and sit down," all would be lovely. But in this scrap he is very well treated, much to my satisfaction.

At the same time I must admit that there are salesmen on the road who are unfit to have any responsibility regarding the trade, and whose reports are not very reliable about it. Not that they do not mean to do everything for the best interest of their firms, and really work in their way to that end, but they are not adapted to the work naturally and lack experience, and that careful training in business necessary to qualify them to go on the road.

It might be possible that some employers are not altogether able to distinguish and point out the best course for their salesmen to pursue, and, perhaps, are carried away with the idea that their goods will sell themselves. Consequently the salesman is but a small part of the show, and is paid accordingly.

As the matter now stands, better prices might have been obtained for stoves this year. The foundation had been made for it, but evidently some of the manufacturers had lost confidence in associations, and while they put on a virtuous front regarding holding prices they possibly did the best they could under the circumstances. But, in reality, they helped make the circumstances as much as any one else. If they are satisfied that they are better off going it alone, let them keep at it and time will tell the story.

So far as making money in the business is concerned (and I don't call patterns, plant and machinery money) the large concerns have just as hard a row to hoe as the small ones, but with this advantage: they have a prestige gained in the past as well as the present to sustain them.

It is generally conceded to be hardly the thing for a salesman to criticise the employers; but it would be a great advantage if we all could be put in the pattern shop, as it were, and then be sent out next season with the very latest and best ideas that can be had, and not with the least salaries that are worthy of the laborer. I am well aware that what comes from salesmen is received with more or less shrugging of the shoulders and elevating of the eyebrows, and with patronising and wise saws and histories of "what we used to do" and boasts of "what we will show them next year" by the man behind the desk. But, bless his dear heart, he spends most of the time with his salesmen talking through his hat.

I take it all in very respectfully, as it would be very nice to have it go his way; but long experience has taught me that there are others who will have something to say, and I will be one of the first to hear of it. And he will rave when he hears of it from me just the same as he does every season. Poor fellow, why can't he learn that the buyer, with his dollars in his pocket, has an arbitrary power, though we work him whenever we can?

The Canadian Stove Trade.

A number of the leading stove manufacturers of Canada met in Hamilton, Ont., last week to consider the question of prices. The outcome was a decision to allow prices to remain unchanged. Commenting upon this action, *Canadian Hardware* says: "In view of the high price of iron and steel, a reduction in figures was not to be expected. And from what we can learn the prices now ruling are fixed upon a moderate basis when cost of material and labor is taken into consideration."

"The turnover of stoves and furnaces in Canada during the season now nearly closing is easily the largest in the experience of the manufacturers of this country. The season of 1900 was considered an usually good one, but the present will doubtless, from what we can gather, exceed it by nearly 50 per cent."

"This increase entailed a heavy tax upon the manufacturers, for early in the season their stocks became so broken up and their orders so far behind that many of them were driven nearly to their wits' end."

"The demand for stoves and furnaces is now getting into small compass, as far as the manufacturers are concerned, although quite a respectable number of orders are still going out."

"What the next season will produce, as far as prices are concerned, cannot with certainty of course be foretold. At present, however, the conditions do not favor a lower range of values. The iron and steel markets continue in a very strong position. During the past month or two there have been quite substantial advances and some foundry grades of pig iron have advanced \$1 per ton within the last few weeks."

The Monarch Line for 1902.

There has always been a striking individuality about the Monarch vapor and oil stoves and asbestos ovens made by the Monarch Stove & Mfg. Company, Mansfield, Ohio, and for the coming campaign the company have greatly increased this important feature by incorporating in every pattern, from the most complete family range to the cheapest Low Junior, a number of special features said to be entirely original with themselves, so that Monarch agents will be greatly profited in pushing Monarch goods next year. The company say that their new catalogue is going to be the most beautiful edition ever issued by them. It will be ready for distribution on January 1.

They also inform the trade that they will be ably represented in New York City at 284-286 Pearl street; in Philadelphia, Pa., at 107 North Second street; in Pittsburgh, Pa., at 203 Wood street; in Chicago, Ill., at 67 Lake street; in St. Paul, Minn., at 191 Eagle street, and in Cincinnati, Ohio, at 419 Pike Building. Their representatives at each of the points named will carefully look after the interests of the company, and will serve the trade in the most satisfactory manner. The company promise the best sellers on the market, and only ask for an opportunity to show their line. Monarch goods, they say, do their own talking, and are "bread cast upon the waters."

SCHELLHAMMER & SON, Warren, Pa., state that they have had a continuous demand for their Pennsylvania Gas Hot Air Furnaces, not only in what is the regular season, but steadily throughout the year, up to the present time. They have been unable to supply all of the demand for these goods and are looking for good hot air furnacemen so as to enable them to increase their output.

CALCULATIONS FOR FURNACE WORK.

It is probable that by far the greater proportion of the furnace work done throughout the country is carried out without any systematic calculation. Experienced furnacemen find less need for rules and tables for their guidance than do men who are just taking up this branch of business. The need of tables and data that will enable men who do not possess a long experience to guide them in designing successful furnace plants is manifest, however, in the frequent inquiries for information of such a character. The various articles which have appeared in *The Metal Worker* from time to time, in which the existing proportions between different parts of a system have been presented, frequently have been the subject of comment by men who take a deep interest in the welfare of the furnace trade. The following extracts, taken from letters that have been received commenting on such articles, are presented for the information of our readers:

A Western house of standing in the trade say:

The practical usefulness of the tables published will undoubtedly be very great to agents and dealers who make a business of selling and installing furnaces. A good practical furnaceman who has had a wide range of experience in hot air furnace heating by the gravity system will usually be able to determine at a glance what will be required to heat the ordinary dwelling—that is, so far as concerns the sizes of pipes, registers, &c.—without any reference to tables. Tables, however, are very essential to the furnaceman who has not had experience in estimating and installing plants where peculiar or unusual conditions exist.

We should also be glad to see *The Metal Worker* take up the subject of ventilation in connection with furnace work. A great many furnacemen, not having a comprehensive experience, do not fully appreciate the fact that much depends upon a good and free circulation of air in the rooms to be heated, and do not know just how to go about exhausting air from rooms which are inclined to be tight and in which there is poor circulation.

The representative of another furnace concern of a wide experience makes the following comments on a recently published description of a furnace plant:

In going over this heating plant we find the sizes in the table presented agree with the sizes of pipes and registers we have found satisfactory in putting in furnaces. We believe that tables of that kind are of great service, and would enable many furnace dealers who know very little about installing a furnace properly to do satisfactory work. Our opinion is that the cold air inlet, especially when the air is taken from the inside of the building, should be equally as large as the warm air outlet. When the air is taken from the outside we advocate the use of an opening one-quarter smaller than the hot air outlets. We advocate the use of 10-inch pipes for the majority of rooms on the first floor, and 8-inch pipes for rooms of similar size on the second floor, with 12-inch pipes for the hall.

A Western manufacturer, who has made a specialty of furnace fittings, remarks:

The table presented in connection with the description of a furnace system, so far as the proportion between the hot air pipes and the work done is considered, corresponds quite closely with our experience in this field. Possibly, as time goes on, the furnace setter will be willing to be guided and governed more by tables of such a nature than has heretofore been found by us. We feel that such information will be productive of general good to the furnace trade.

An Eastern manufacturer states that a test is being made to demonstrate the value of a system of estimating furnace work, as the necessity for such a system that can be relied upon has been felt where it is impossible to send an expert furnaceman upon the ground to give the necessary assistance in laying out a piece of work.

ANNUAL MEETING AND BANQUET OF THE PENNSYLVANIA STOVE SALESMEN'S ASSOCIATION.

The fifth annual meeting and banquet of the Pennsylvania Stove Salesmen's Association was held in the Bourse banqueting rooms, Philadelphia, Pa., Wednesday evening, December 18. The attendance was the largest which has ever assembled at any of the previous meetings of the association. Among those present may be mentioned:

W. G. Withers, W. F. Habicht, H. G. Knight, H. Kircher, W. W. Farr and H. Borzell of F. M. Borden & Brother, Philadelphia.

Geo. L. Woodburn, H. V. Jennings, L. B. Campbell, Jos. Evans and D. Zelenski of Mahood & Co., Philadelphia.

Jno. R. McKnight, W. Hallowell and F. Neudorfer of the Mt. Penn Stove Company, Reading and Philadelphia.

F. Cavanaugh and A. Colquhoun of the Quakertown Stove Company, Quakertown and Philadelphia.

Harry McDowell, W. P. McConnor and L. Johnson of Liebrandt & McDowell Stove Company, Philadelphia.

Froing Riggs of C. C. Heath & Co., Baltimore and Philadelphia.

H. J. Morgan of the Lehigh Stove Company, Lehigh-ton, Pa.

E. F. Fager of the Keeley Stove Company, Columbia, Pa.

H. Dunlap of Isaac A. Sheppard & Co., Philadelphia, Pa.

Geo. W. Wagner of Floyd, Wells & Co., Royersford, Pa.

A. A. Miller of *The Metal Worker*, Philadelphia.

J. McLaughlin of *The Pattern Maker*, Philadelphia.

Fred. Sabin, J. G. Waters, E. Belson and Geo. W. Moss of Philadelphia, and last, but not least, Harvey Fueller of Reading, Pa., the man who has done much to make the association a success by his untiring efforts as toastmaster on various occasions.

The members and guests of the association entered the banquet room to the music of the "Tea Kettle Orchestra." The president, W. G. Withers, made the address of welcome and introduced, amid applause, Harvey Fueller of Reading, as toastmaster for the evening, after which the following banquet was served:

MENU.

Medium Salts.	A la Cross Piece.
Celery.	De Covers.
Olives.	Ze Lifter.
Radishes.	Ah Leg.
Consomme Windsor.	Vin Poker.
Filet of Sole au Vin Blanc.	Au Shaker.
Filet of Beef, Madeira Sauce.	Och Runner.
Peas.	Duplex Pattern.
Potatoes.	His Knobs.
Punch Yvette.	
Roast Squab en Casseroie.	Hot Air.
Lettuce Salad.	
Neapolitan Ice Cream.	
Cakes.	
Cigars.	

During the course of the banquet all present were called upon by the toastmaster for a "few remarks," "to make a speech," "sing a song," or "whistle a tune" and each in turn responded in a happy manner. The feature of the evening was a poetical creation by the vice-president, Geo. Woodburn, which follows:

A SALESMAN'S REVERIE.

The custom is with modern scribes who wish to pen their lines,
To seek some theme on which to build that happened bygone times;
But here events of future days our Muse will now relate,
And paint her fancy as she sees the model hero's fate.

One score years advance from now will dwell in a mansion grand
A gray haired Sire of stature great with wealth at his command;
The place at which his vast estate will rise in grandeur then
Will be among the Berkshire hills not far from Mountain Penn.

Within his palace will be rooms and many spacious halls,
With etchings of the greatest men to thus adorn the walls;
But set apart is a gorgeous space most private for the Sire,
Where he will rest in quiet thought before an open fire.

His leisure hours by cozy hearth reclining in a chair;
The clouds of smoke from his cigar that curl up in the air,
Are times that prompt fair Muse to tell a little prophesy,
Of what this Sire will oftentimes dream in silent reverie.

Quoth he: "This winter's night is cold; without is a raging storm,
Myself will draw unto the hearth that I may feel the warm,
And by this swift electric spark will light a fresh cigar,
And think of friends of ye olden times that wander near and far.

"This puff of smoke, the first is large—I see within its fold
The visage of a millionaire, his Fortune was never told;
His craft was that to fashion tin, a master of the art;
He bore the name of Sabin, and a hustler from the start.

"Just as the smoke is vanishing I behold another face;
Yes, two more forms appear to me of our Caucasian race;
Beneath the shady Beechwood together there they sit—
Friend Cavanaugh and A. Colquhoun, who lately made a Hit.

"Another cloud of smoke I draw and from my lips unfold,
And now I see a tourist of the Bengal regions old;
From his heated brow he wipes the sweat beneath a Rosemont Oak—
'Tis Wagoner, a man of wealth and financier of note.

"But what is this I now must view from out the passing cloud?
Two forms I see with Ulsters that around them form a shroud;
They are rivals for the heart and hand of some Columbian Charm;
'Tis Busick and his jolly smile, with Fager on his arm.

"A puff of smoke I again give vent, and this is what I see—
A Victor like some Hercules of very high degree;
He stands there like a statue, his face doth bear no scowl;
I recognize his features as a friend of mine, McDowell.

"Still another vision presents itself in that fading curl,
As if by Magic it seems to try a pennant to unfurl;
The noble face I sure must know, a chum in days of yore;
'Tis Dunlap whose lips now speak the word Excelsior.

"Once more a cloud of smoke released, the other seems to chase,
And in it is a personage with Sunshine on his face;
His life was one of wit and mirth, I never saw him sad,
'Tis Othello's son, brave Sheeler, a very jolly lad.

"Just here I'll knock the ashes and take a cleaner smoke—
Behold a face with details that no lips have ever spoke;
It seems that he is longing for a fragrant Lehigh Rose,
For Morgan was delighted when he wore one on his clothes.

"Now comes another vision great that one must surely heed—
I hear four voices singing, I see Reinking in the lead,
There's McKnight, Neudorfer, Hallowell—this song they sing
so free—
'Queen Esther, O Queen Esther, thou art all the world to me.'

"Again I'll draw some precious smoke, and what does it contain?
I see a hat of straw come first this cold night in the rain;
An Oxford student, I believe, with Black Jack up his sleeve,
'Tis Withers out for a promenade with Miss Bonnie Novelty.

"But what form is this so distant in that great cloud of smoke—
There seems to be a Stove Pipe hat, a full dress High Grade coat;
A diamond, too, in a white shirt front, a Dandy size and real,
'Tis Habicht, surnamed Chauncey, a great toaster at a meal.

"Another group is coming as the mists pass o'er my head—
There is Knight, the man of credits, no Idol life he led;
There is Farr, the hearty laughter, one wired me a Dispatch;
Borzell and Kercher, I see them too, they were a Handy match.

"Some ashes I again let fall and greater fumes expel—
There beneath a Canopy are two figures I know well;
One holds a pen like Homer and Coin the other shows;
They are Hopkins and my old friend Fox, whom everybody knows.

"Above me now is curling a swiftly flying mist.
Within its folds I see a saw and compass in a fist;
I hear a voice speak softly, he is telling a comic yarn;
'Tis McLaughlin, the pattern maker, he ne'er lived upon a farm.

"But who is this I next will view in the winding, passing curl,
A form no taller than a babe, a face like some sweet girl;
But larger now it seems to grow, yes, truly getting great.
'Tis one who claims a Grand Ideal, friend Riggs, of this good State.

"One more puff I now will take, my cigar is nearly gone;
Behold a New Flag up there waves in a hand both firm and strong,
There seem to be two visages, the last has a Classic smile;
'Tis Evans and friend Campbell, both are noblemen of style.

"But here comes one large, misty curl, it hovers o'er me now,
I see the features of a friend with an intellectual brow;
He seems to be of cast iron will, bricked up with honesty,
He holds a letter in his hand signed, 'Yours, D. P. Z.'

In this fume just passing now is presented to my view
A personage that sure will win some Valley Queen so true;
He stands there quite attentive, I believe he has a bride,
'Tis Jennings, that chum of mine, with Lady Irving at his side.

"But here at last my fire is out, this stump I'll throw away,
My quiet pastime now is o'er until some other day;
A pleasure oftentimes brings me to think of ye old times,
When with the boys I used to tour through many sunny climes.

"These visages that I have seen were friends of mine, not foes,
Who traveled by rail, by boat, by 'bus o'er country selling stoves;
Through many hamlets they have passed, and every dealer know—
I really hope they've had success since twenty years ago."

Just here the silent reverie of gray haired Sire must end,
And Muse will now his name disclose and to all a message send—
Once a commercial tourist, but a man of wealth that day,
This Sire will then be Fueller, the scribe of P. S. A.

'Tis a forethought for the future, not of the ages past.
This prophecy is now made known and such predictions cast
That members of S. S. A. of P. around this festive board
In closer union may be drawn while present times afford.

The future lies before us, boys, the past has fled by,
The present now within our grasp this knot should closer tie,
And when in one score years to come we may in mansions be,
Our happiest pastimes will be spent in A Salesman's Reverie.

The retiring president, Mr. Withers, was presented on behalf of the members of the association, with an artistic reproduction of a "Southern Pickaninny," Mr. Campbell making the presentation speech. H. Dunlap entertained the members with several recitations, Geo. W. Moss told "How he was a speech maker," and W. F. Habicht, by special request, was asked to "tell the story of his life." "Shop talk" was tabooed throughout the evening.

The business session of the association was short, consisting of the election of officers and a discussion of plans for the enlargement of the association. It was suggested that the secretary place himself in communication with the various employers of stove salesmen, requesting the names of their men.

The following officers were then elected for the ensuing year:

President, George Woodburn.

Vice-President, H. Dunlap.

Secretary, W. Hallowell.

Treasurer, Fred. Sabiu.

A vote of thanks was tendered the retiring officers, and after drinking toasts to the absent ones, "sweethearts and wives" and the President of the United States, the most successful meeting and banquet of the Pennsylvania Stove Salesmen's Association came to a close.

Award of Prizes in "Acorn Bread" Contest.

Rathbone, Sard & Co., Aurora, Ill., have announced the list of winners of prizes in the "Acorn Bread" competition for 1901. The prizes were awarded at Aurora on Thursday, December 5, by a committee of three ladies appointed for the purpose. Samples of "Acorn Bread," numbered from 1 to 473, were submitted to the committee from the States of Illinois, Indiana, Ohio, Wisconsin, Minnesota, South Dakota, Nebraska and Kansas. The committee examined all of the samples of bread submitted for their inspection, and unanimously decided, under the rules of the contest, that the prizes for 1901 should be awarded as follows:

FIRST PRIZE.—Sample No. 147, baked in the National Acorn range by Mrs. E. Sieckenberger of Chicago.

SECOND PRIZE.—Sample No. 198, baked in the Bessemer Acorn steel range by Rosa A. De Groodt of Excelsior, Minn.

THIRD PRIZE.—Sample No. 219, baked in the Fern Acorn wood cooking stove by Mrs. T. H. Crumpacker of De Kalb, Mo.

Special mention, with award of Acorn gold charms, was given the following:

No. 403, Mrs. Lizzie Hamm, Shelby, Mo.

No. 169, Mrs. J. H. Pederson, Milwaukee, Wis.

No. 9, Mrs. L. Minton, Chicago.

No. 133, Mary E. Whitmer, Milford Center, Ohio.

No. 50, Mrs. Amos Ladwig, Hawkeye, Iowa.

No. 79, Mrs. L. M. Murphy, Cody, Neb.

No. 8, Mrs. John Meyer, Joliet, Ill.

No. 111, Mrs. Byron Cook, Keokuk, Iowa.

No. 194, Mrs. Martin K. Anderson, Minneapolis, Minn.

Charles W. Goodnough.

Chas. W. Goodnough, who has been the sales manager of the Pittsburgh Stove & Range Company since their organization, tendered his resignation some weeks ago, to take effect on the 16th inst. Mr. Goodnough resigned his position to become the Pittsburgh manager for the Prizer-Painter Stove & Heater Company of Reading, Pa., who will open a branch office and warehouse in Pittsburgh for the purpose of supplying the trade in Western Pennsylvania, Ohio, West Virginia and Western Maryland. Prior to the consolidation of the stove interests in Pittsburgh Mr. Goodnough was a member of the old established firm of De Haven & Co., and largely assisted in promoting the Cinderella stoves and ranges, which are well known throughout the country.

ODD PLATES.

THE SHERIDAN STOVE MFG. COMPANY of Quincy, Ill., are meeting with a very gratifying demand for their goods. The capacity of the works is so taxed at present that President J. L. Sheridan expresses the belief that it will soon have to be increased. Cyrus W. Eaton and J. C. Shanks of Denver, Col., were in the city early in December and closed a deal with the Sheridan Company for over 3000 Stoves, which as soon as completed are to be shipped to Denver. We understand that this is the largest single order for Stoves that the company have ever received.

THE JAPANNING plant of the Eclipse Stove Company of Mansfield, Ohio, had a narrow escape from serious damage a couple of weeks ago. A stick of dynamite was found in one of the japanning ovens, having attached to it several matches and connected with a fuse, the evident intention of some one being to await a suitable opportunity to set it off. Fortunately the attempt was not successful, for had it been there is no telling the amount of damage that would have been done.

THE EQUITABLE FURNACE COMPANY of New York City were incorporated this week with a capital stock of \$50,000.

THE H. ADLER COMPANY, Pittsburgh, Pa., are sending to the trade in the interest of the Acme Gas Stoves and Ovens a calendar which is a handsome bit of color work. The calendar tablets are quite small, and attached to one corner, the feature of the card being the portrait of a Persian beauty.

THE WALKER & PRATT MFG. COMPANY, Boston, Mass., are sending to the trade leaflets adapted for advertising purposes showing cuts of their Home Crawford and Charm Crawford Ranges. The different cuts are designed to attract attention to special features of these Ranges, such as the easily removed nickel rails, method of manipulating the grate, the use of the simmering cover, the regulating damper, the oven heat indicator, the method of cleaning the flues and the square oven with two racks. All of these special cuts are designated by a number, and those in the Stove trade who desire an advertising cut can secure the size and style they want by including the number of the cut in their request for one.

THE PITTSBURGH STOVE & RANGE COMPANY of Pittsburgh have sold to the American Locomotive Company the property and buildings formerly owned by De Haven & Co., Limited, Stove makers, and located on Preble avenue, in Allegheny. The De Haven plant was taken over when the Pittsburgh Stove & Range Company were organized about two years ago.

C. W. ALDRICH, Minneapolis, Minn., announces to the trade that he has accepted an engagement with the Home Stove Company, manufacturers of Model Stoves and Ranges, Indianapolis, Ind. Mr. Aldrich will travel through the Northwest, and his territory will extend down through Northern Missouri, including Kansas City. Mr. Aldrich is well known in the Stove and Hardware trade of the Northwest, having been prominent in the organization of retail Hardware associations in several States. His interest in the work of such organizations has been recognized by invitations from various associations to read papers before them. The Home Stove Company have reached the eighth year of their existence and have in that time built up a large business in their specialties. They now manufacture a line of 100 different sizes of Steel and Cast Ranges and Cooks, and over 120 different sizes of Oak Stoves, Hot Blasts and Airtights.

THE KEYSTONE MFG. COMPANY of McKeesport, Pa., made their first heat last week, and are now running steadily in the manufacture of Stoves, Gas Ranges, Stove Fittings and other specialties. The company are composed of William E. Hartman, James L. Delong, Charles F. Delong, Charles T. Moore, W. F. McCrea and Ralph Harris. The plant consists of a foundry building, 60 x 100 feet in size, and a fitting, machine and polishing shop, 30 x 212 feet, and two stories in height.

THE S. OBERMAYER COMPANY, Cincinnati, Ohio, manufacturers of Foundry Facings and Supplies, are operating their plants night and day. The company have just completed the first shipment of stock to their new warehouse in Pittsburgh, and are now carrying in stock there a complete line of equipment for brass and iron foundries.

THE CHATTANOOGA STOVE COMPANY, Chattanooga, Tenn., report a very satisfactory season, the demand for their goods having been unusually active. The company's plant will be closed down shortly for about two weeks for the annual stock taking and the carrying out of necessary repairs.

THE Quick Meal Gasoline Stoves, the manufacturers—the Ringen Stove Company, St. Louis, Mo.—advise us, are commanding a great and constantly increasing sale on the strength of their name, quality and merit. The name "Quick Meal" has become known everywhere during the past 20 years, and is regarded as a strong guarantee of excellence. In material, workmanship and construction alike the Quick Meal goods are of the highest class, which accounts for their popularity.

RATHBONE, SARD & Co. of Aurora, Ill., and Albany, N. Y., have been distributing among the trade a circular calling attention to the merits of the Acorn Steel Ranges, and to the fact that they differ from Ranges of other makes. Attention is directed to some of the good features of these Ranges, which the dealer is requested to note in connection with Stove Book 5, sent out by the company some time ago. The manufacturers also refer to the Acorn plan for newspaper advertising as being different from others, and which, when used in connection with their newest steel specialties, seldom fails of satisfactory results. The company furnish a complete variety of illustrated newspaper advertisements devoted to the stove business, and more especially to the patterns which their customers are selling. The electrotypes are of uniform size and by the use of them with the name of the dealer added the cost of advertising in the average weekly newspaper is reduced to a minimum.

THE plant of the Round Oak Stove Works, at Dowagiac, Mich., shut down in all departments on Saturday afternoon, December 7, for the purpose of taking the annual inventory and making necessary repairs. The shut down will also be utilized for the installation of a device in the boiler room, which, it is expected, will effect a great saving in the cost of fuel. The new device is calculated to render the consumption of slack possible in the furnaces, in which case coal will be displaced. General Manager Lee states that work will be resumed with a full force in the early part of January, by which time the inventory and improvements will have been completed.

THE MICHIGAN STOVE COMPANY, on Monday, December 16, filed with the Secretary of State, at Lansing, a renewal of corporate existence for 30 years, and notice of increase of stock from \$300,000 to \$3,000,000. An officer of the company is reported by a Detroit paper to have stated that the increase had long been anticipated, but being a close corporation it was necessary to wait for the expiration of the charter. We understand that the company have enjoyed a very prosperous year.

THE TWIN BURNER STOVE COMPANY, 206-210 South Seventeenth street, St. Louis, Mo., have their line of Twin Burner Gasoline and Oil Stoves ready for the new year, and announce to the trade that their catalogue is ready for distribution. The Twin Burner line includes all styles of Stoves, from the four-burner of cabinet form, with oven burner at the side, to the low Juniors. The company's new No. 480 Stove can be used either for gasoline or coal oil.

THE SIMPSON STOVE MFG. COMPANY of Pittsburgh, Pa., have recently filed articles of incorporation at Harrisburg, the capital stock being placed at \$50,000. The incorporation of the company and the increase in the capital stock are said to be due to the growth of business and the intention to materially increase the capacity of the plant. A building covering an area of about 200 x 300 feet will be erected on the 4 acres which the company have secured near Canonsburg, and more than 100 hands will be employed. The officers of the new com-

pany are: H. P. Simpson, president; S. Munnell, Jr., secretary and treasurer, and George A. Simpson, superintendent.

Pennsylvania Retail Hardware Dealers' Association.

The Pennsylvania Retail Hardware Dealers' Association was organized at a meeting held at the Monongahela House, Pittsburgh, on the 12th inst. The entire proceedings were characterized by a unity of purpose and resolution, and the testimony was clear that an organization should be established for mutual protection. About 35 merchants were in attendance.

The meeting was held under the auspices of the Monongahela Valley Retail Hardware Dealers' Association and was called to order by President G. L. Moore of Brownsville, who stated the object of the meeting, closing his remarks with a brief history of the sectional organization. The forenoon session was taken up chiefly with short discussions on existing conditions and proposed remedies. On reassembling in the afternoon M. L. Corey, secretary of the National Retail Hardware Dealers' Association, gave an interesting and very instructive talk on the Indiana State Association, the difficulties it encountered, how some of them were overcome, while others were still unsolved. He urged a united effort to bring about a solution of many difficult problems that beset the trade, giving some illustrations of marvelous results wrought by a steadfast and united effort. He pointed out that organization unites socially, a friendly feeling being thus engendered, which dissipates the deadly competition that often arises through misunderstanding. At the close of his remarks one purpose seemed to animate those present, and that was to establish an organization that all might reap the benefits that have come so freely to those already in the fold. Some discussion arose as to the name of the new association. As the representation was from the Western end of the State it was thought the name of Western Pennsylvania Retail Hardware Dealers' Association would be appropriate. Others thought the scope of the organization should embrace the entire State, and the following resolutions were adopted:

Resolved, That this association be known as the Pennsylvania Retail Hardware Dealers' Association, and that its membership include retail hardware dealers exclusively.

Resolved, That we affiliate with the National Retail Hardware Dealers' Association.

The following officers were elected:

G. L. Moore, president, Brownsville.
Geo. J. Rudolph, vice-president, Pittsburgh.
J. F. Frye, secretary, Charleroi.
B. A. Maggini, treasurer, Braddock.

EXECUTIVE COMMITTEE.

A. Q. Casselberry, Pittsburgh.
E. E. Lyon, Greensburg.
C. N. Savage, California.
B. A. Maggini, Braddock.
C. O. Shroyer, Dawson.

The association then adjourned to meet on the second Wednesday in February at the Monongahela House, Pittsburgh. This date is, however, subject to change.

It is gratifying thus to note that the retail hardware merchants of the great State of Pennsylvania have swung into line for self defense by means of an association, and it is hoped that the present membership may be largely augmented before the next meeting in February. Any information desired in regard to the association will be cheerfully furnished by Mr. Frye, the secretary.

Southwestern Kansas and Oklahoma Implement and Hardware Dealers' Association.

The second annual meeting of the Southwestern Kansas and Oklahoma Implement and Hardware Dealers' Association was held in Wichita, Kan., on the 4th and 5th inst. in the council chamber of the City Hall. S. H. Myton of Winfield, Kan., occupied the chair, and a large number of members were in attendance. Among the papers read at the convention were those by B. B. Breed of the Studebaker Bros. Mfg. Company, South Bend, Ind., on "The Relations of the Dealer and Mar-

manufacturer from a Traveling Man's Standpoint," and by D. W. Blaine of Pratt, Kan., on "The Supply and Demand for Prison Binder Twine, from a Dealer's Standpoint." The following officers were elected for the ensuing year: President, Charles Watson, Pond Creek, Ok.; vice-presidents, John Baumstark, Harper, Kan.; S. H. Myton, Winfield, Kan. Directors: F. M. Spangler, Mulhall, Ok.; W. H. Hubbard, Conway Springs, Kan.; Henry Noble, Alva, Ok.

The Willis Sap Spout.

The Hunting-Weekes Company, Watertown, N. Y., are offering the sap spout herewith illustrated. It is made in one piece of malleable iron, tinned. It is pro-

Fig. 1.—The Willis Sap Spout, Open Top.

vided with anchoring lugs to safely retain the spout in the tree when the sap freezes in the hole during extremely cold weather, and to prevent it being drawn

Fig. 2.—The Willis Sap Spout, Closed Top.

out by the weight of the bucket, or leaking when the sap begins to thaw. The manufacturers state that the spout cannot break, that it does not clog, and that it does not obstruct the flow of sap from the vertical pores of the tree. The spouts are made open and closed tops, and to fit a hole bored with a 1/2-inch bit.

Stove and Hardware Dealers.

THE FRANKLIN GALVANIZED WARE MFG. COMPANY, Franklin, Ind., have lately been incorporated with the following officers: P. W. Payne, president; D. A. Forsyth, vice-president; W. B. Jennings, secretary; A. F. Curtis, treasurer, and W. H. Unversaw, manager. The office, factory and warehouse of the company are nearing completion. Nearly all their machinery has been contracted for, and they will begin installing it about December 23. They purpose to manufacture nearly all kinds of Galvanized and Japanned Ware from the sheets—that is, Galvanized Steel Tanks, Tubs, Buckets, Half Bushel Measures and various other articles, including the filling of special orders for heavy Galvanized Steel Tanks. The company expect to have their plant ready for operation about January 15, 1902.

THE Executive Committee of the North Dakota Retail Hardware Association have decided to hold the next, the fifth, annual meeting of the association in Fargo, February 19 and 20, 1902.

THE next annual convention of the Illinois Retail Hardware Dealers' Association will be held at Decatur on February 12 and 13.

MCDOWELL & GRAVES are successors to McDowell & Pettigrew in the wholesale and retail Hardware, Stove, Farm Implement and Buggy and Wagon business in Cahool, Mo.

RIPON HARDWARE COMPANY, Ripon, Wis., have been organized and have bought the stock of Shelf and Heavy Hardware, Stoves, Tinware, Sporting Goods, Furnaces, &c., formerly carried by Charles Cowan.

H. J. STUCHBERY has lately opened up a new stock of Hardware, Stoves, Sporting Goods and furniture in Ringwood, Oklahoma.

JONES, BYRD & Co. are a new Hardware concern at Limestone, Tenn., handling in addition to Shelf and Heavy Hardware, Stoves, Tinware, Agricultural Implements, Cement, Lime, &c.

J. E. FARRELL, Hyde Park, Mass., has recently taken possession of his new building. His line comprises Shelf and Heavy Hardware, Stoves, Tinware, Agricultural Implements, Sporting Goods, Seeds, &c. Mr. Farrell reports a satisfactory business, with a promising outlook for the future.

KOLF HARDWARE COMPANY, Hobart, Oklahoma, have recently embarked in business at that point, handling both Shelf and Heavy Hardware, Stoves and Agricultural Implements.

FRISBEE & SEXTON have succeeded Sharp & Frisbee in the Hardware and Stove business in Long Beach, Cal.

WATERMAN HARDWARE COMPANY, Geo. Waterman, president and treasurer, Albany, N. Y., have lately opened a new store at 141 South Pearl street. They are carrying a full line of Hardware, Tools, Kitchen Utensils, &c.

W. F. HUNT has purchased the Spore Steel Fence Post Company's factory in Newark, N. Y., and will convert it into a manufacturing plant for Anti-Rust Tinware.

THE NATIONAL ENAMELING & STAMPING COMPANY, New York, are announcing a large and complete line of Railroad Milk Cans for 1902. The company began the manufacture of these goods a few years ago and are now among the largest producers in the United States. They advise us that they have experienced a remarkable growth in this particular line of business. Dealers who are interested in these goods would do well to write the company for the little 40-page booklet which they have gotten out in the interests of their Railroad Milk Cans, Factory Cans and Dairy Supplies, of which they manufacture a complete line.

An Effort to Abolish Strikes.

The conference between representatives of capital and labor, under the auspices of the National Civic Federation, as announced in our last week's issue, took place on Monday and Tuesday in the rooms of the Board of Trade and Transportation in New York City. The meeting was attended by about 200 people, including the heads of several of the largest industrial organizations, representing many millions of capital, and most of the prominent leaders of labor organizations, representing hundreds of thousands of workingmen, also a number of prominent persons representing the general public.

Oscar S. Straus, ex-Minister to Turkey, called the meeting to order and introduced the first speaker, Bishop Potter of New York, who congratulated those present upon the gathering, than which he believed nothing more important had ever happened in the history of the great social and industrial problem. The bringing together of the great forces of industrial activity in a comity of intercourse and conference was, in his judgment, the largest step in the direction of a solution of the problem of capital and labor that had ever yet been taken.

Senator Hanna of Ohio followed and, in the course of his remarks, made the statement that the grandest thing that could be accomplished in this country would be the successful movement to bring capital and labor into closer relations of confidence and reliance. The Senator said that he would rather have the credit of bringing about such a consummation than be President of the United States.

Among the subsequent speakers were Archbishop Ire-

land of St. Paul; John Phillips, secretary of the Hatters' Union; Representative Donnelly of the Bricklayers' Union, James Ryan of the Photo-Engravers' Union and Marcus Marks of the Clothing Makers' Union, all of whom took the line that disputes between men in their trades and their employers could in nearly all cases be settled by arbitration.

William H. Pfahler of Philadelphia, president of the National Association of Stove Manufacturers, made one of the most telling addresses of the conference in describing the experience of the association formed by the employers in the stove trade. Mr. Pfahler said:

We organized an association at that time—and it was a great many years ago—for defense. We began that association to defend ourselves against the aggressions of the Iron Molders' Union. We worked along those lines two or three years, fighting each issue as it rose. But we very soon learned that our point was wrong; that our approach to the question was wrong, and we changed the policy of that association to be one of negotiation, to be an association which should, from our standpoint, show the men who were in our employ the condition of affairs from their standpoint, learn the condition of their lives and industries, and to co-operate upon a line which would produce the best results.

There has not been a strike in the stove industry. Why? We have approached that subject through representatives of each body, and if there is anything valuable in this country to-day it is the representative system, so long as these representatives are well qualified men to carry out their purposes.

President Charles M. Schwab of the United States Steel Corporation, another of the speakers, expressed his opposition to labor unions as at present organized. In giving his reasons for this opinion Mr. Schwab said:

That labor unions will never succeed, as trusts never succeeded, by attempts to restrict the output or attempts to put any restriction upon trade in general.

These great trusts that are formed in a business way to control the output of any commodity, to raise its price, they all have failed and all will fail. A trust will succeed where there are motives of consolidation for economy's sake and for regulating trade generally.

And the laborer must take a similar position. Labor must not restrict the output. That is a fundamental principle. And I am sorry to say that every labor organization with which I have had experience in the past has had as its foundation the restriction of the output.

He added:

I should not be opposed to organized labor if organized on correct principles. It is a mistaken idea to suppose that manufacturers are opposed to labor organizations, *per se*. They are opposed to them as they do exist; not to labor organizations who keep their contracts, not to labor organizations who will not restrict the output, not to labor organizations who have the good of the trade they represent at heart.

At the meeting on Tuesday a motion was adopted for the appointment of a standing committee to take the subject of labor troubles under further consideration, and formulate a plan to obviate strikes in the future. This committee to be composed of 12 representatives of organized capital, 12 of organized labor and 12 to represent the general public. The following is the committee, as appointed by Chairman Straus:

ON BEHALF OF THE PUBLIC.

Grover Cleveland.
Cornelius N. Bliss.
Charles Francis Adams.
Archbishop John Ireland.
Bishop Henry C. Potter.
Charles W. Eliot, president Harvard University.
Franklin MacVeagh, Chicago.
James H. Eckels.
John J. McCook.
John G. Milburn, Buffalo.
Charles J. Bonaparte, Baltimore.
Oscar S. Straus.
Ralph M. Easley.

REPRESENTATIVES OF ORGANIZED LABOR.

Samuel Gompers, president of the American Federation of Labor.
John Mitchell, president of the United Mine Workers.
F. P. Sargent, Grand Master of the Brotherhood of Locomotive Firemen.
T. J. Shaffer, president of the Amalgamated Association of Iron, Steel and Tin Workers.
James Duncan, secretary of the Granite Cutters' Association.
Daniel J. Keefe, president of the International Association of Longshoremen.
Martin Fox, president of the National Iron Molders' Union.

James E. Lynch, president of the International Typographical Union.

Edward E. Clarke, Grand Conductor, Brotherhood of Railway Conductors.

Henry White, secretary of the Garment Workers of America.

Walter MacArthur, editor of the *Coast Seaman's Journal*, San Francisco.

James O'Connell, president of the International Association of Machinists.

REPRESENTATIVE EMPLOYERS.

Senator Marcus A. Hanna, Cleveland.

Charles M. Schwab, president United States Steel Corporation.

S. R. Callaway, American Locomotive Works.

Charles Moore, president National Tool Company.

J. D. Rockefeller, Jr.

H. H. Vreeland, Metropolitan Street Railway Company.

Lewis Nixon, Crescent Shipyard, Elizabethport, N. J.

James A. Chambers, president American Glass Company, Pittsburgh, Pa.

William H. Pfahler, president National Association Stove Manufacturers, Philadelphia, Pa.

E. P. Ripley, president Atchison, Topeka & Santa Fé Railway.

Marcus M. Marks, president of National Association Clothing Manufacturers.

J. Kruttschnitt, president of Southern Pacific Railway Company.

A subcommittee was appointed to consider and formulate suggestions for plan and scope of this permanent committee. The general sentiment of the meeting on both Monday and Tuesday seemed to be that a peaceable way out of labor difficulties could always be found by amicable and free discussion of the questions at issue between employers and their employees, and that these ends could be best served by the existence of a standing committee in which both sides should be represented.

Among the speakers on Tuesday was E. D. Durand of Washington, secretary of the National Industrial Commission, who cordially indorsed the plan of a committee of arbitration and conciliation and characterized it as the most practical method of obviating labor troubles. Grand Master Sargent of the Locomotive Firemen also spoke in a similar vein, from the point of view of labor, and was followed by several other labor leaders, as well as Lewis Nixon, the shipbuilder, of Elizabethport, N. J. President Mitchell of the Mine Workers said that he had never seen a strike which could not have been averted if the employers and men had met in conference, and a similar opinion was expressed by Samuel Gompers.

On Wednesday a meeting of the standing committee was held, at which Senator Hanna was elected chairman, Samuel Gompers and Oscar S. Straus, vice-chairmen; Charles A. Moore, treasurer, and Ralph M. Easley, secretary. A further meeting of the general committee will be held in the latter part of January, when by-laws will be adopted and the general plan of action will be decided upon.

A LARGE CARD, to which a calendar is attached, which is being distributed among the trade by the Vance Boiler Works of Geneva, N. Y., manufacturers of the Vance Boilers for steam and hot water heating, presents a realistic scene in a boiler makers' shop. In the foreground are the bellows and forge for heating the rivets, while just beyond is a large boiler shell with the workmen engaged in riveting the parts together. The picture is in black and red. The glare of the fire has been used with a very striking effect to light up the whole scene.

THE UNITED STATES RADIATOR COMPANY, Dunkirk, N. Y., are sending to the trade an announcement of the opening of a branch office at room 68 of the Corcoran Building, Washington, D. C., in charge of M. E. Danforth, who is well known to the trade in that vicinity. The new office has been established in order that the interests of the trade in that territory may be more carefully and promptly cared for.

THE PHILADELPHIA STEAM HEATING COMPANY of Philadelphia, Pa., have taken out permits for installing new steam heating plants to the amount of \$31,000, the largest of which is a \$19,000 contract for the new theater which is being erected by B. F. Keith, on Chestnut street, above Eleventh street.

European Heating Boilers.

BY CHARLES F. HAUSS.

IN THREE PARTS. FIRST HALF OF PART THREE.

[Continued from *The Metal Worker*, December 7, 1901.]

The Crosius boiler, shown in Figs. 95, 96 and 97, is made for steam only in two models and in 13 sizes, with 40 to 178 square feet of fire surface. It has about twice the water contained in the boiler just mentioned, but holds much less coke, averaging only 1 pound of coke per square foot of surface. It is also rated to supply 3000 heat units or 10 square feet of steam radiation per hour. Fig. 97 shows the arrangement of the safety pipe, also

the flow and return headers. A particular feature of this boiler is the flow header, which, for water, is a plain hollow tube, while in the steam header an inner tube is introduced with openings in the top through which the steam enters the main pipe at the front, as indicated by the arrows. The function of this pipe is to prevent entrained water from being carried with the steam. The fire travel is shown by the arrows, going up on each side in the flues marked 1 into the upper flues 2, thence back and down on each side, rising again in the center, where it finds its exit in the smoke flue, making it a reversible flue boiler.

Figs. 103 to 105 show the latest creation, known as the Rapid boiler, having, for steam, what are termed American trimmings, as shown in Fig. 103. In Fig. 104 is

Fig. 95.

Fig. 96.

Fig. 97.

Fig. 98.

Fig. 99.

Fig. 100.

Fig. 101.

EUROPEAN HEATING BOILERS.

the float damper regulator; in fact, it is a German boiler "trimmed."

Fig. 98 represents a cast iron drop tube boiler made by the Luisenhütte, and which is a correct copy of the Furman boiler so well known in America. The double cylinder arrangement on the front is the automatic regulator and safety pipe connection combined.

Figs. 99 to 102 show the Bolze boiler, with a large central magazine, water grate and a separate wrought iron base forming the ash pit. It is made with from 4 to 18 sections, increasing two sections at a time, the sections being $4\frac{1}{2}$ inches thick, with from 64 to 230 square feet of fire surface. The boiler is rated to supply 2600 heat units or 14 square feet of water radiation and 9 square feet of steam radiation per square foot of fire surface per hour, and has about the same proportions of water contained and fuel capacity as the Strehla boiler, shown in Figs. 89 to 94. The sections in this boiler are connected with wrought iron nipples and lock nuts to

shown the same boiler for water, without the steam dome, and in Fig. 105 is indicated its construction. It is made in two patterns and 17 sizes, with 38 to 179 square feet of fire surface, and is rated to the limit—namely, 20 square feet of water radiation or 13 square feet of steam radiation per square foot of fire surface. It has about 3 pounds of water, and holds about $1\frac{1}{2}$ pounds of coke per square foot of surface. The sections are joined together in the crudest manner with gaskets and bolts.

Figs. 106 and 107 show the new Bolze round boiler, which is surely a freak, being a wrought iron pipe coil with a heavy cast iron shell cast around it, the excuse for its existence being that it supplies a long felt want in the shape of a round fire pot cast iron boiler that will not crack; also that it has a large fuel reservoir. It is made in two sizes only, rated to supply 4800 and 8000 heat units per hour. Surely the desire to avoid risk in the foundry must have overcome the inventor's desire for efficiency in this case.

In Figs. 108 and 109 are presented the Nitchke portable magazine return flue boiler, made of wrought iron, in which the products pass up through the inner tubes and down the outer ones into the smoke chamber surrounding the ash pit. This is a very efficient, substantial boiler.
(To be continued.)

WHAT IS WRONG ?

In conversation with a plumber and stove dealer, a correspondent finds what may be considered unusual conditions. A review of the plumber's business career and the position in which he finds himself at the present is given by the correspondent as follows without comment:

When he started business four or five years ago the

Fig. 102.

Fig. 103.

Fig. 104.

Fig. 105.

Fig. 106.

Fig. 107.

Fig. 108.

Fig. 109.

EUROPEAN HEATING BOILERS.

plumber began in a small way with a shop only. He worked himself when necessary and also superintended jobs. The venture proved successful and the business paid well.

Within two or three years the town had grown in size to between 5000 and 6000 inhabitants, and he thought he could branch out with advantage to himself, especially as there were two other shops of the same general character which carried stoves and kitchen ware. He had also got to a point where he felt that he could afford to let his workman do all the manual labor, while he devoted his time to superintending work.

He had an idea, too, that he might gain prestige by putting himself more prominently before the public. So he rented a nice store, with show windows, in a good location, and put in a stock of stoves, granite and tin ware, &c.

While he carried a well assorted and attractive line of goods, competition was sharp. In addition to the other stove stores a department store sold stoves, kitchen ware, furniture and house furnishing goods, and

their prices on the line he carried were lower than he could well afford to meet. In addition all the dry goods and grocery stores carried some tinware, so that when a customer wanted a tea kettle, wash boiler, pans, &c., they were in a position to supply their requirements. Many stoves, too, had to be charged or sold on the instalment plan, with some accompanying loss. As the result, he found that the profits from goods sold barely paid rent, fuel, lights, insurance, &c., and the wages of a clerk to attend to the store while the proprietor was out.

He feels that it would be a retrograde step to abandon the stove part of the business, and that it might injure his standing in the community. His shop business continues to bring him satisfactory returns, but he is getting nothing for the risk and additional burden of carry-

ing a stock of goods. He says if there is any consolation in the thought, he has good grounds for believing that he is getting returns from his store equal to any of his competitors, but he expresses regret at ever having put in a stock of goods, and believes that he would have been better off if he had confined himself to plumbing, and had not yielded to the temptation of branching out.

THE UNION LEAD & OIL COMPANY, who are half owners in the Federal Lead Company, recently organized under the laws of New Jersey with a capital stock of \$10,000,000, are making a purchase of real estate and erecting suitable factories in different parts of the country. Homer Wise, president of the company, whose offices are at 32 Nassau street, New York, has recently, it is said, completed negotiations for the absorption of the Raymond Lead Company of Chicago. It is also stated that a new White Lead manufacturing plant is contemplated at Alton, Ill., near the smelter of the Federal Lead Company.

KEEPING TRACK OF JOBS.

C. F. Hamblin, St. Augustine, Fla., has a system of keeping track of jobs, in connection with which a time book, daybook, contract book and ledger are used. One of the office force keeps track of every workman's location, each workman making a verbal report to the clerk when any piece of work, large or small, is started, and another report when the work is finished. These reports are entered on the time book when made. A sample page of the time book is shown in the accompanying cut. At least an entire page is used for each day, and more if necessary.

The left hand column of the page contains the names of the workmen. The second column is headed "store," and is used for the time of workmen employed in or about the store. The other columns are devoted to the name of the party or job on which the workman is employed. The figures at the left of each column denote when work was begun, and those to the right show when it was completed. Each morning a clerk checks the time book for the preceding day, and posts each workman's time to his account in the ledger. The page to which it is posted is marked in red ink on the time page immediately below the record of time. The time on each

exposure of a large amount of heating surface with which the air passing through the apparatus can come in contact. The steam generator enables rooms at a considerable distance from the heater to be heated by means of direct or indirect steam radiators. The first few pages are devoted to a description of the heater, grate and ash pit section and general construction. The remaining 30 pages each bear a half-tone engraving of some fine residence or institution in which the Demarest improved heater has been used, testimonial letters speaking of the satisfaction derived accompanying each of the engravings.

Utilizing Waste Heat from Steam Mains.

The construction of the tunnels used for the steam pipes running from the central heating plant at the University of Chicago involves novel features. The problem is to carry steam underground without losing too much heat. The common practice is to wrap the pipes with a nonconducting substance to confine the heat within, but it is figured that even under favorable conditions some heat is lost. Engineer Houghton has solved the problem by a system of subways surrounded by air chambers and

Keeping Track of Jobs.—Sample Page of Time Book.

job is also entered on a page in the contract book devoted to the job. By the time book it can be seen at any time during the day how any workman is employed, and inside of a minute it can be as readily seen how many men were at work on any certain date, as well as where each and every one was at any particular time.

When a workman or helper needs material he gets it from a clerk, who waits on him in the same way as he would on any other customer. The clerk makes an entry of the material in the daybook, one page of which is devoted to each job. The material is also entered on the contract book and charged to the job on which it is used. Material taken out for any job and not used is credited on the contract book. When a job is completed the items of labor and material are extended and footed up, so that the results of each contract can be readily seen. The amount of the charge is then posted from the contract book to the ledger account of the individual for whom the work is done.

The Demarest Heaters.

The Innes & Demarest Heating Company, Binghamton, N. Y., are sending to the trade a handsome catalogue devoted to the Demarest steam and warm air heating apparatus, which they say has been tested from Maine to Minnesota with universal satisfaction. The heater is adapted for either portable or brick setting, and consists of a porcupine fire pot with a steel plate combustion chamber, in which a steam generator is located. Exit from this combustion chamber to the smoke pipe is found through a down draft drum or radiator, so that the construction provides for a long fire travel and the

concrete, and he has the advantage of having his pipes exposed in a tunnel where they may be easily got at.

There is a main tunnel running under Ellis avenue to the campus, where it divides into three branches. This tunnel measures 10 x 5 feet inside. It contains five 12-inch, two 8-inch and two 6-inch steam mains, besides a number of cables for carrying electric light and power. On each side it has a double brick wall, with a 2-inch air space between the two sections. The base is concrete, and conduits for the electric cables are formed by rows of brick, which are covered by a wooden floor. The top is insulated by an air space, a layer of asbestos and a concrete covering. It was necessary to have these tunnels near the surface of the ground because of the water struck at a depth of 6 or 7 feet.

As there would be a poor chance for vegetation to grow above the tunnels, on account of the dryness, and heat, the idea was conceived of so locating them that they could be covered with artificial stone walks and roadways, which was done. It is believed the escaping heat from the tunnels will keep the walks free from snow during the winter and dispense with the services of the shovel brigade.

A SUIT was brought in Paris, France, by a tenant against his landlord, after the latter had refused to start the heating apparatus on October 23, when the thermometer was standing at the freezing point. The landlord declined to provide heat before November 1, on the ground that the latter date accorded to custom. The Court decided that the thermometer and not the almanac must be consulted in regard to the time fires must be started for warming apartments rented with heat.

NEW YORK MASTER PLUMBERS' ENTERTAINMENT.

The annual entertainment and ball of the Association of Master Plumbers of the City of New York, Manhattan branch, was held in the Lexington Opera House, Fifty-eighth street, New York, on Wednesday evening. The entertainment was in charge of the following committee: Milton Schnaier, chairman; B. F. Donohoe, treasurer; T. J. McCormack, secretary, and John Boyd, S. L. Malcolm, T. J. Tuomey, J. F. Kelly, T. J. Cummins, J. W. O'Brien, C. Tucker, T. F. McCaul, G. F. McQuillen, E. J. Brady, Alex Bryant, Isaac J. Brown and T. A. Hill. The opera house was nearly filled with members of the association and their ladies, with a good representation of the wholesale plumbing trade of New York City and Brooklyn.

The entertainment opened with a variety programme of nine numbers, the overture being rendered by Professor William Bayne's Sixty-ninth Regiment Band. The early part of the evening was spent in enjoying this entertainment and in visiting among the various boxes and floor seats. The social side was a prominent feature of the entertainment, and the color effect lent by the costumes of the ladies was very pleasing.

The last number of the programme was an illustrated song.

The Committee of Arrangements had had pictures made of ex-National President Samuel L. Malcolm, president of the Manhattan branch; A. H. Brown, president of the Greater New York Association; I. J. Brown, the well-known plumbing statesman; Jonas A. Rossman, and the Chesterfield of the plumbing trade, Thomas J. Tuomey. The presentation of these pictures was accompanied by appropriate remarks as they appeared. At the close of this part of the programme the floor was cleared for dancing, and the grand promenade was formed to the music by Bayne's Band. After the promenade began the usual stir, caused by filling in of the dancing programmes, to be quieted by the first strains of a seductive waltz. Dancing was continued until a late hour.

Among those present were Alderman McCaul, Joseph McCann of the Missouri and Pacific Railroad, C. A. Walsh, William Kirchof, Jonas A. Rossman, John Yule, E. J. Riordan, John Renehan and Frank Reynolds.

NEW RADIATOR COMPANY.

Papers are being prepared for the incorporation of the New York Radiator Company, to manufacture steam and hot water radiators in Utica, N. Y. The new company will be conducted in conjunction with the Hart & Crouse Company, the principal stockholders in the new company being connected with that concern. Those who are chiefly interested are: Frederick T. Proctor, H. Gilbert Hart, Charles B. Rogers, president of the First National Bank of Utica, and Joseph Rudd. A plot of 8 acres has been secured in East Utica, situated on Turner street, adjoining the Erie Canal, and convenient to the Broad street railroad switch.

Designs for the buildings of the new plant are now being drawn by the superintendent of the Hart & Crouse Company. All of the buildings will be of brick construction, the largest being the foundry. There will also be a large machine shop and warehouse. It is expected that the plant will be completed and in full operation early in July. The machinery for the equipment of the plant will be of the most approved modern type for turning out a large amount of work, accurately finished. Designs for a very handsome and complete line of steam and hot water radiators have already been selected, and the patterns are in course of completion.

The company will have the advantage of experienced management, having a thorough acquaintance with the trade. The same men will be at its head that have made a success of the Hart & Crouse Company, who have established a large trade for the Royal line of steam and hot water heaters and hot air furnaces. Their customers should insure the sale of a large proportion of the output of the new plant. It is expected that the plant will have a capacity to enable the company to put upon the market a larger number of square feet of radiation than was ever put on the market by any new concern in its first year of business.

Vanderman's Improved Roof Connection for Soil Pipe.

In the accompanying illustrations we show a new roof fitting for plumbers' use, manufactured by the Vanderman Heating & Plumbing Company of Willimantic, Conn. In Fig. 1 a general view of the fitting is presented, and in Fig. 2 a sectional view, from which it can be seen that a perfectly air tight connection can be effected, which allows free expansion and contraction of the pipe passing through it. It is claimed that this fitting makes a better finish on the roof, and, extending 12 inches above and 15 inches below the roof, there is no danger of leakage. It is also pointed out that no tools are required on a

Fig. 1.—General View.

Fig. 2.—Sectional View.

Vanderman's Improved Roof Connection for Soil Pipes.

roof for making the joints. These fittings are made for 2, 3, 4, 5 and 6 inch pipe, only in the medium weight, which can be used for either standard or extra heavy soil pipe.

Spokane Galvanized Wire Pipe.

An interesting method of manufacturing wooden water pipe has been developed by the Spokane Galvanized Wire Pipe Company, Spokane, Wash. This pipe is manufactured of kiln dried Oregon fir. The staves are dressed to true mathematical segments, which when assembled form a perfect circle. The pipe is made in standard 8-foot lengths, around which galvanized wire is spirally wound. In winding the wire is paid out under tension adapted to the size of the pipe and wire. The spacing of the wire, as well as its size, is adapted to the pressure under which the pipe is to serve. Thus the higher the pressure the larger the wire used and the closer it is wound. The staves are well dressed, making the inside of the pipe smooth. The wire is double galvanized to insure its longevity. The wood is thoroughly kiln dried to evaporate the sap. The pipe is thoroughly boiled in asphalt to more completely protect it from destructive agencies. Each joint of the pipe is made with a socket and spigot end, enabling joints to be easily made. It is stated that the only tools necessary in joining the pipe are wooden mauls to drive the joints together. The manufacturers claim that the life of this pipe is from 15 to 20 years. It is further claimed that if the water passing through the pipe should freeze the pipe will not burst as the wire imbeds itself in the wood, the expansion being taken up by the wooden staves. This pipe is finding a large field of operations in sections of the West requiring a cheap pipe for irrigation purposes.

O. CHAN WELLS, 26 Cortlandt street, New York, who has represented the United States Tube & Iron Company, has added the Monongahela Tube Company of Pennsylvania to the list of mills of which he is an agent. He is quoting prices for Boiler Tubes, both steel and charcoal iron, for this company. They make a complete line of Lap Welded Boiler Tubes from 1 to 16 inches in diameter. They also make extra sizes and thicknesses if specifications are furnished.

The Lake Erie Specialty Mfg. Company.

The Lake Erie Specialty Mfg. Company, Geneva, Ohio, have lately been organized under the laws of that State. The following are the officers of the concern: T. H. Russell, president; E. M. Converse, vice-president; V. L. Atkins, secretary; C. I. Chamberlain, treasurer, and J. H. Lyons, superintendent. The company will manufacture a line of plumbers' brass goods, including Lyons' special patented goods. At present they are ready to quote prices on and supply promptly Fuller bath cocks, Fuller basin cocks, stop and waste cocks, sill cocks and compression work of all kinds. As fast as competent men can be secured and more machinery can be installed they will increase the line on this class of goods and bathroom fixtures in general, so as to make it as complete as any. We are advised that the company have a well equipped plant, are amply financed, and that the business is managed by experienced men, who are intending to produce a high grade of goods.

New York City Notes.

The most costly plumbing job in the city will be that of the apartment house being built by the Astors at Fifty-fifth street and Fifth avenue, which will probably amount to around \$150,000. The contract has not yet been given out.

Geo. Essig of 37 Hancock place has the plumbing contract for an apartment at Manhattan avenue and 116th street.

Manhattan branch presented to the family of the late M. J. McDermott a handsomely engrossed set of resolutions.

One of the features of the enjoyable entertainment given last Wednesday evening was the violin solo given by Milton Schnaier, who was also chairman of the Committee of Arrangements.

The remarks made at the entertainment in connection with the picture of ex-National President Malcolm of his habit of looking up soldiers' monuments in convention cities will be appreciated by all who know him.

The many friends of William Young of 32 East Fifty-ninth street will be glad to learn that he is getting better of an injury to his knee received from a fall, and which confined him to the house for some weeks.

The plumbing shop of Murphy Bros., at 175 East Eighty-second street, was totally burned out last week. Pierce Murphy, the senior partner, has for many years been foreman for Milton Schnaier & Co., and only lately went into business for himself. He is now located at Lexington avenue and Eighty-second street.

If plans to be figured on show anything of work to be done, next year will be a very busy one. There are many model tenements to be built and a number of high-class elevator apartments on the upper West Side, together with downtown business buildings. Every plumber doing this class of work is busy figuring on plans for the same.

Plans have just been filed for an apartment house at Lenox avenue and 112th street under the new Tenement House law. This is being watched with a great deal of interest by the building trade, for, if successful, it will revive interest in this class of buildings, no plans for which have been filed since July 1.

The New York State Commissioner of Public Safety, D. W. Peck, has reprimanded a plumber of Syracuse, N. Y., for violating the plumbing rules and regulations. He states that the public welfare demands that plumbing and sanitary rules be strictly enforced and lived up to.

Officers of Manhattan Branch Master Plumbers' Association.

The Manhattan Branch of the Greater New York Master Plumbers' Association held their annual meeting on Tuesday evening, December 17, and elected the following officers for 1902:

- President, Andrew H. Brown.
- Vice-President, B. F. Donohoe.
- Treasurer, Philip Brady.
- Recording Secretary, T. A. Hill.
- Financial Secretary, A. W. Reynolds.
- Sergeant-at-Arms, T. J. McCormack.
- Marshall, Wm. Kirchhof.
- Trustees: T. J. Tuomey, Chairman; Alex. Bryant, E. J. Brady, M. J. O'Brien, T. J. Cummins.

The following were elected as representatives in the Greater New York Master Plumbers' Association: B. F. Donohoe, John Renahan, T. F. McCaul, T. J. McCormack, G. F. McQuillen, T. F. Gaynor, W. J. McDermott, T. J. Cummins, J. T. Coyle, Milton Schnaier, J. F. Kelly, Frank Reynolds, E. J. Brady, J. A. Rossman, J. W. O'Brien, Isaac J. Brown, Philip Brady, Isaac O. Shumway, A. E. Jackson.

The P. & S. S. League.

Higher scores and closer contests characterized the bowling on Monday night in the Plumbing and Steam Supply League tournament in New York. The following teams each won and lost a game: John Simmons Company, Behrer & Co. and Ronalds & Johnson Company, Brooklyn. The John Simmons Company team lost their first game and broke their series of continuous victories. W. T. Gilmour made 198, the high score of the evening. On Thursday night the John Simmons Company team lost another game, and the Thomas G. Knight team lost two, while the Crane Company team wound up the bowling for the year with two victories, to which S. Marx contributed a score of 204 in one game. The next meeting of the teams will occur on January 6.

The Standing of the Teams at the Close of the Year.

Teams.	Won.	Lost.	Indi-		Name.
			Team	vidual	
			score.	score.	
John Simmons Company	3	2	779	196	W. A. Presby.
Behrer & Co.	6	2	827	198	M. Behrer.
Crane Company	6	2	798	210	A. E. Good.
Ronalds & Johnson Company, Brooklyn	7	3	827	198	W. T. Gilmour.
Ronalds & Johnson Company, New York	5	3	702	189	W. S. Gibbs.
Salesmen	3	3	742	222	Henry Stein.
F. N. Du Bois & Co.	6	4	776	202	C. W. Frean.
Central Foundry Company	6	4	701	199	J. S. Dibley.
Dlmock & Fink Company	4	4	772	194	F. Hogenauer.
C. S. Locke & Smith	4	4	693	193	C. A. Blanchard.
H. P. Read Lead Works	4	5	689	196	C. V. Driggs.
John A. Murray	2	6	676	189	G. W. Tilton.
Thomas G. Knight	2	6	675	182	E. E. Benas.
Fred. Adee & Co.	2	8	695	175	A. B. Kolyer.
E. F. Keating	0	8	601	185	C. J. McCarthy.

Heating and Plumbing Notes.

The semiannual meeting of the Master Steam and Hot Water Fitters' Association of the State of New York was held at the Yates Hotel, Syracuse, on December 10. The principal feature of the meeting was a discussion of the petition to be presented to Congress calling upon the United States Government to have the power, heating and ventilating plants and other portions of building contracts let by separate contracts instead of by the present system, which allows the contracts to be awarded to one general contractor, who then has the privilege of subletting the contracts. Action was also taken to advocate a similar plan for the public works of New York State.

JACQUES LAFERME, the Paris representative of the Standard Mfg. Company of Pittsburgh, is now in this country on a business visit.

The iron mills of the Republic Iron & Steel Company, at Muncie, Ind., are having steam boilers set over the puddling furnaces for the purpose of saving fuel. At one mill three of these boilers are used, and two others are

being built. At another mill there are three such combined puddling furnaces and steam generating plants; two other furnaces are being reconstructed so that the heat from them may be utilized for generating steam in boilers.

THE BURLEY HEATER COMPANY, Tyrone, Pa., have had a very prosperous season. In addition to their manufacture of Hot Water Boilers, the company have now begun to make Iron Castings of all descriptions.

A FIRE, doing damage to the extent of \$400, visited the plumbing establishment of the Colman & McGar Company, Bridgeport, Conn., last week. The loss is entirely covered by insurance.

A PLUMBING supply company, with a capital of \$30,000, are about to erect a new factory at Quincy, Ill., for the manufacture of Plumbing Goods.

THE ROYAL HEATING COMPANY of San Francisco, Cal., recently installed a No. 47 Prince Royal Combination Warm Air and Hot Water Heater in the residence of a customer, to heat six rooms and halls on the first floor and seven chambers and bathrooms on the second floor. One of the hot air pipes extended 45 feet for heating two of the rooms. The customer states that the work has been in every way satisfactory. The company also installed a No. 30 Wood Royal Furnace for heating a church at Visalia, and a No. 56 Royal Air Furnace was used by them for heating a church at Fresno. In these churches, it is stated that thermometers placed in the four corners of the buildings showed the variation in temperature to be less than 1 degree.

W. E. DONNELLY, Chicopee Falls, Mass., has the contract for the plumbing in the factory of the Knit Goods Specialty Company.

A HOUSE, in which Carey & Son, Rochester, N. Y., were doing the plumbing, was broken into recently and \$30 worth of plumbing tools were stolen.

EDWARD MAHL of Hartford, Conn., is plumbing two houses for W. H. Scoville. He has just completed plumbing contracts for T. F. Brabazon and A. W. North, and is now engaged on the work in the Wethersfield Avenue School House, in his city.

THE State House Commission of Louisiana have let the contract for a steam heating system for the new Capitol building to F. G. Butler of Greenville, at his bid of \$26,500.

C. L. GRANT of Hartford, Conn., has secured the contract for installing a refrigerating plant in the new brewery at Allington, Conn.

WALTER G. RUGGLES has sent in his resignation to the International Pump Company, and will open an office at 85 Water street, Reading, Mass., as a representative of the National Pipe Bending Company of New Haven, Conn.

F. I. LESSARD & Co. are now established in new quarters at 40 Hampden street, Springfield, Mass., where they are well equipped for doing a plumbing, gas fitting and steam and hot water heating business. They have the contract for plumbing a building for the Shaker colony, at Alfred, Maine.

WATROUS & BARKER, 131 Dwight street, Springfield, Mass., heating contractors and metal workers, report considerable activity in the demand for furnace work in their territory.

J. H. MAKIN, Springvale, Maine, has secured the contract for the plumbing and heating apparatus for the new Sanford High School Building, in that town.

W. E. FRYE of Crestline, Ohio, has opened a plumbing shop at the corner of Center and Prospect streets, Marion, Ohio.

CONTRACTS for additional heating apparatus at the city buildings at New Britain, Conn., have been awarded to J. B. Weiant and George Rapelye.

THE DETROIT HEATING & LIGHTING COMPANY, Detroit, Mich., are sending to the trade a catalogue 12 x 16 inches in size, consisting of 18 plate pages, illustrated with half-tone engravings, showing a great variety of Gas Lighting Fixtures, Chandeliers, Side Brackets and Globes. The catalogue is accompanied by order blanks arranged so as to avoid the possibility of error in ordering.

HENRY W. GRELLE, a plumber, of 2207 St. Louis street, New Orleans, La., has invented an air propeller to be used on small sailing boats. By the use of a small model he has demonstrated that boats using a propeller can run as easily in the face of the wind as with it. The propeller may be revolved by a small engine or dynamo.

MARVIN W. KINGSLEY, for 28 years superintendent of the Cleveland, Ohio, Water Works Department, has opened offices in the Rose Building, that city, and will devote his attention to civil and hydraulic engineering pertaining to the erection of water works plants, &c.

THE KENNEDY & SULLIVAN MFG. COMPANY, Holyoke, Mass., steam and hot water heating, tinning, plumbing, &c., have leased the building adjoining their plant and will build an addition to the Brass foundry 25 feet long and two additions for storage purposes. Most of the additional room will be used for the manufacture of Mr. Sullivan's patent Anti-Water Hammer Hydrant, which they are about to put on the market, and for the manufacture of Brass Valves.

THOMAS DEVLIN & SON, Philadelphia, Pa., manufacturers of Malleable Iron Fittings, Castings, &c., are negotiating with the local improvement association of Burlington, N. J., for the removal of their plant to that place. Though nothing definite has as yet been decided, there is a possibility that Burlington will get the works, as the firm are at present very much in need of more room.

THE LUNKENHEIMER COMPANY, Cincinnati, Ohio, makers of Steam Fitters' and Brass and Iron Steam Supplies, are well along in the construction of their main building at Fairmount, Cincinnati. The size of the building is 190 x 375 feet, to be four stories and basement when completed. Owing to the fact that they have been badly delayed in securing structural material, the delay being largely occasioned by the steel strike, they will not be able to complete the structure before next spring, and will hardly be in their new quarters before June 1, 1902.

THE WILLIAM POWELL COMPANY, Cincinnati, Ohio, makers of Brass and Iron Fittings and Steam Supplies, are again enlarging their plant, this being the second addition they have made to it during the present year. The new building is 50 x 35 feet, and three stories high, and adjoins the plant in the rear. The latest departure in manufacturing which this company have entered into is that of injectors. They are just getting out their patterns, and expect to be active competitors in that line from now on.

GEORGE L. KING, who was formerly a member of the King Mfg. Company, of Pittsburgh, Pa., is again about to start in the Plumbing Supply business. He desires to communicate with manufacturers and jobbers regarding the goods they are likely to need. Mr. King recently sold out his interest in the King Mfg. Company. His present address is 128 Fourth avenue, Pittsburgh, Pa.

New Firms and Changes.

D. O. MILLER, Rutland, Vt., has sold a half interest in his Stove and Plumbing business to his brother, William Miller. The new firm will begin business on January 1.

MORTIMER H. FIELD has purchased the Plumbing, Heating, Tinsmithing and Stove business conducted by his father, Benjamin P. Field, at Main and Willow streets, Babylon, N. Y., since May 1, 1853, and will continue the business at the old stand.

THE HEATING APPLIANCE COMPANY OF AMERICA have been incorporated under the laws of Maine, with a capital stock of \$150,000, for the purpose of acquiring and using letters patent relating to Automatic Heat Regulating Appliances. The president of the company is N. T. Merritt, Jr., of Boston, and the treasurer is Fred. H. Talcott of Boston.

THE LITTLE GIANT STOKER COMPANY of Chicago have been incorporated, with a capital stock of \$5000, by E. T. Wray, H. L. Kraft and A. J. Adams, to manufacture Power Generating and Heating Apparatus.

T. F. CROWN has bought a half interest in the plumbing business of T. Fleming at Brattleboro, Vt.

JOHN F. LARCOME has left Beachmont, Mass., to open a plumbing shop in Norfolk, Va.

What Should a Cornice Maker Know?

The question as to what a cornice maker should know, which was brought to the attention of the readers of *The Metal Worker* in last week's issue, is answered differently by several master cornice makers. Some think that he should be familiar with every detail of cornice making, from cutting the patterns to finishing the work on the building. Others claim that he should be an expert in but one or two branches of the trade, and that the man who is thorough in all the branches should be designated as a foreman.

Some very interesting experiences are given as to how educations in the trade were obtained and helpful suggestions are made that should be of value to young men with ambition and grit who desire to advance to the front ranks. The following is an extract from a letter received from a New Jersey employer:

From my experience of 30 years in different countries I expect a cornice maker to be a man who, under the guidance of a foreman, can solder and rivet moldings, brackets or any other ornaments that have been already cut and formed properly and swiftly. Some of these men gain the special ability of putting work on the buildings where often judgment of circumstances as well as some knowledge of geometry is required. It is certain that only a very small percentage of cornice makers are able to lay the work out and finish it themselves. Persons who can do this are generally advertised as foremen or cutters. Those in the first category know hardly anything about drawings and only the latter ones must understand them perfectly. There is, in all large shops, chance for any of these to have good employment providing they do their certain work right. I would call the first two classes cornice workers, either on the bench or on buildings, or both, and only the latter class cornice makers.

THE WRITER'S TRAINING.

I received a common public school education in Germany up to 14 years of age. During the last three years there, like all other boys, I had some instruction in drawing and in general geometry. From my fourteenth to my eighteenth year I learned the tinsmith's trade. During the winter months we apprentices could visit a Sunday school for practical geometrical drawings in their respective branches. Some bosses compelled their boys to attend that school and questioned them frequently about their progress.

At the age of 19 years I went to a large city and applied for work in a cornice shop, although never having seen a cornice made. I was set to work soldering together brackets, &c., but not being satisfied with such work I took every spare moment and examined the drawings lying around in the shop, asked questions of the cutters and studied. My knowledge of geometrical drawing and my ambition, although being only a tinsmith, helped me so that in less than four weeks I was advanced to assistant cutter, and in seven weeks became a gang boss, while some of the men under me had been there for years, and never improved. I have worked since in different places and finally in my own shop made many difficult pieces of work with comparatively little reference to books.

PUBLIC SCHOOLS SHOULD BE MORE PRACTICAL.

I attribute my success mostly to the fact that I learned geometrical drawing in my youth, that I took pleasure in it and improved myself in it by utilizing my spare time in the study of it. If our present public schools would expend more time and energy in instructing boys in geometrical drawing intermingled with free hand drawing, and if this was done by experienced male teachers I judge the boys would prefer to learn trades instead of becoming office boys, schemers or something else. Geometrical knowledge and drawing in general is good in all positions in life. If taught generally we would have less trouble in producing good mechanics.

DEFINITIONS BY A BALTIMORE EMPLOYER.

The definition of a cornice maker, as given by a Baltimore employer, is as follows:

There are several classes of cornice makers; the ordinary man, the good man and the foreman, all of whom are mechanics in their particular class. In many shops there are good steady men, who cannot lay off or get out patterns for, but can solder, rivet, put together and put up the various kinds of metal work under instructions from or guidance of the foreman.

A man who would enjoy the title of a first-class cornice maker should have a fair knowledge of drawings, making patterns for his miscellaneous work. Should he aspire to the position of foreman he should possess a fair education in drawing, mathematics and pattern cutting and be familiar with the necessary cornice making machinery and able to estimate from drawings. In short, a mechanic, whether he be a cornice maker or otherwise, should never be done learning. For the beginner we believe it absolutely necessary that he should devote much of his time during apprenticeship to attending a drawing school. He should also provide himself with a first-class pattern book.

PRESENT GENERATION NOT ANXIOUS TO LEARN.

The head of a Boston house thinks that the great trouble is with the young men of the present time, who do not seem anxious to improve themselves. He says:

The young men of to-day do not seem to catch on to the importance of what they should really learn. All they seem to care about is to get through the day and get their money Saturday night. Once in a while we run across a young man who will ask questions and will try and pry into things, to know the reason why they are done, and who asks questions in regard to cutting work and breaking work up on the machines. In our shop we take young men to learn the trade and put them on all classes of work and give them a chance to cut and form up on the machines. Since we have put in our large brakes, run by power, we have broken in two or three of the young men, taught them how to work them and then have put them to the bench again to finish their trade. We think the trouble to-day is more with the boys themselves in not trying to help themselves by asking questions. If they would go to evening schools it would be a great help to them.

EMPLOYERS MIGHT TEACH EMPLOYEES.

The president of another Boston cornice making concern thinks that employers could profitably help teach their men. He writes:

I think it very essential that a cornice maker should be a tinsmith before becoming a cornice maker. I first worked three years in a tin shop, and I have always felt that I was greatly helped by my knowledge of tinsmith machinery and the methods employed in making tinware. Every man who takes to cornice work should learn to cut patterns when he first starts in. We have experienced a great difficulty in getting men to take charge of work. Men that have worked for us 15 or 18 years have apparently never thought it worth while to learn to cut patterns or improve themselves any further than to do a good day's work with tools. It seems to be a fact that the men do not care. They have no ambition. If the employers would set aside an hour or two once a week for instruction, the men would doubtless take kindly to it, and the benefit would be mutual. Or if the different shops in the city would open a night school for all cornice makers it would be a paying institution.

A FOREMAN'S EXPERIENCE.

The foreman of a Jersey City sheet metal working house furnishes us with the following valuable contribution:

A cornice maker should know his business thoroughly. He should not be content to learn only one branch, but should persevere until he has mastered the entire trade, from drawing to finishing work upon the building. How can he do this? By perseverance and hard study.

Why are there so few thorough cornice makers? 1.

Lack of confidence. 2. Lack of interest in their business. 3. Unwillingness to devote spare time to hard study.

It is easy to understand why a boy can learn the mechanical branch and know how to put work together without learning the art of pattern cutting. He is profitable from the beginning as an apprentice or helper. As he learns the use of tools he is advanced. He learns to make cornices by helping older mechanics make them.

PATTERN CUTTING.

The pattern cutter needs no apprentice. His work must not be intrusted to unskilled hands. One mistake on his part might cause the loss of a great deal. To be a pattern cutter one must study and become proficient in the art of cutting, and know the principles upon which the work is done. This is within the reach of every bright, energetic young man working at the trade. The first thing to do is to get a good book on pattern making. There is none better than "The Metal Worker Pattern Book." Then devote a reasonable amount of time to study, and there is no reason why one should not succeed. There are very few cutters who do not take pleasure in explaining a difficult problem, or showing one who is willing and trying to learn.

Pattern cutting is a fascinating study, and if once taken up in earnest it becomes a pleasure more than a duty. It is always encouraging to know there is a chance for improvement ahead.

SHOULD KNOW ALL BRANCHES.

The following interesting communication comes from a prominent New England sheet metal worker:

A cornice maker should know everything about his business that it is possible to know. The cornice business has developed into the art of working sheet metal entirely for buildings, and therefore it is not enough for a cornice maker to know how to work sheet metal, but he should know all about buildings and all about drawings. It is true that if he is not ambitious and is willing to work all his life for \$3 a day all he need bother his head about is to acquire the knack of putting work together after it has been got out for him, and putting it up on the building after the foreman shows him how it is to go and where. But if he wants to advance himself and earn the highest possible wages, or get into business for himself, he needs to make a serious study of drawing. He should first go into an architect's office for six months without pay, and make full size details from 1/4-inch scale drawings. That will be excellent practice. If he cannot spare the time to work in an architect's office let him attend night school.

PERSPECTIVE. &c.

He wants to know how to draw sections through buildings, walls, foundations, cornices, sections through windows, plans and elevations, the same as an architect would. He should know something about perspective, so that when he sends an order into his shop for additional work he can make a sketch in perspective which will give an accurate idea of what he wants and so save many words. After he has learned the elements of architectural drawing then he wants to learn pattern cutting, developing sheet metal moldings in the flat. He should learn a little something about designing, especially if he has a taste for such work, and also something about modeling in clay. All these things are adjuncts of the architectural sheet metal business. The more he knows of such things the better equipped he is. If he has no time to go to night school, or if there is none in his town, let him take a course by mail through a correspondence school.

He should cultivate his imagination. He should be able to picture in his mind moldings standing out in the air, so that he can see them almost as plain as if drawn. Then he can study in his idle moments these images sticking out in the air, and find out the best plan of cutting a pattern from them.

EMPLOYERS SHOULD EDUCATE WORKMEN.

It seems to us that if the employers would take up the matter of educating their workmen, they would find it greatly to the mutual advantage of both the employer

and employees. Let the employers apply one hour of the shop's time on Saturday afternoon to giving a lecture to all of the workmen in the shop on pattern cutting, architectural drafting, the best way to put up work and the best way to put it together. A half an hour's talk might be made by a competent leceurer with black-board sketches, and another half hour spent in discussions by the workmen on what they have just heard or on matters pertaining to the business. This would be the most profitable hour that the employer would be paying for. It would set the young fellows to thinking during the evenings and the hours of their work. It would present their work to them in a new light and it would put them in the way of helping themselves.

I know of one man who has been in business for 25 years, and yet in his shop there is not a man who has grown up with him whom he could pick out and put in charge of the shop to cut patterns, or anything else in that line. It is simply on account of this policy of letting everybody shift for himself. The boss watches the men to see that they do not loaf, and the men watch the clock to see that they do not work too long. The Saturday hour lecture would change all that, and bring the employer and workmen together in a new and favorable light and show that their interests are mutual.

PATTERN FOR APPLE CORER.

A useful little article that can be made from scrap tin, with all seams and joints soldered, is an apple corer. The full size dimensions and method of obtain-

Front and Side View and Pattern of Apple Corer.

ing the pattern for the corer are shown in the accompanying illustration, in which A B C D is the side view of the corer, soldered to the handle E at the top, with an opening on the line C D, which forms the blade which cuts into the apple, while the opening 1' 3' 1" allows the core to be taken out. The section through the corer is shown by F in plan. H I J K L shows the front view, K representing the circular blade, M the opening and N the joint. The round disks G and G at the ends of the handle are slightly convex, and assume that shape when using the hollow punch in punching the disks.

To obtain the pattern for the corer proceed as follows: Divide the half plan F into an equal number of spaces, as shown by the small figures 1 to 5.

Parallel to B C and from these small figures draw lines intersecting the blade line D C, the core opening at 1', 2', 3', 2" and 1", and the handle E, as shown. Now at right angles to B C draw any line, as O P, upon which place twice the number of spaces contained in the half plan F, as shown by the small figures 1 to 5 to 1 on O P. Through these intersections and at right angles to O P draw lines indefinitely, as shown, which intersect with lines drawn from points of intersections on D C, 1' 2' 3' 2" 1", and on A B having similar numbers, as shown in the pattern. A line traced through points of

Intersection thus obtained, as shown by R S T U V W X Y Z, will be the pattern for the corer. The pattern for the handle is not shown, as that simply consists of a tube as long as from H to I in front with a diameter equal to E in side view, having the convex disks soldered on same to close the ends.

ALLOWING LAPS ON PATTERNS.

In *The Metal Worker* pattern cutting articles, all patterns, unless it is otherwise stated, are shown net—that is, no laps are allowed for seaming, riveting or wiring. These must be added, as required, by the pattern cutter when cutting the metal.

It is the usual practice for wiring to add to the height of the pattern three times the thickness of the wire in use. For a soldered or riveted seam a lap on one side of the pattern is all that is required; while for a grooved or locked seam edges or laps must be allowed on both sides of the pattern. Care should be taken when making allowance for a grooved seam, so that a single edge is allowed on one side and a double edge on the other. While this seems a simple matter some allow double edges on both sides.

To better illustrate these points, Fig. 1 shows five diagrams lettered A B C D and E. A represents a pattern to which the allowance has been given for wiring. The radial lines X and X are continued as shown, which

Allowing Edges for Wiring, Soldering, Riveting and Grooving.

will be the proper lines to notch and not notch off the corner, as shown at Y, which is sometimes done.

Diagram B shows a pattern to which a soldering edge has been added, as shown at H. In this case a lap is only required on one side of the pattern. A portion of a wiring edge has been allowed, showing how it should be notched at the corner J.

Diagram C shows a pattern to which a riveting edge has been allowed. In work of this kind the holes for riveting should be punched before the pattern is rolled up. In this case, as in the soldering edge, a lap on one side of the pattern is required, as shown at K. Through the center of this lap, at proper divisions, holes are punched as shown. Now, assuming that the distance from the line of the pattern V to the center of the holes is equal to L, then place this distance on the opposite side of the pattern, measuring from the line of the pattern W and obtain the distance M equal to L; then, using the center of the pattern, describe arcs *e*, *f* and *j*, thus obtaining the rivet holes in their proper position, so that when the article is rolled the holes will come over each other.

In diagram D is illustrated a grooved seam, showing the amount of edges which must be allowed. Thus *a* is where the pattern would meet were no edges allowed. By following the diagram, *b* shows why one edge is al-

lowed to one side of the pattern in diagram E, as at N, while *c* and *d* in diagram D shows why two edges must be allowed on the opposite side of the pattern in diagram E, as at O and P. Thus one side has a single and the other side a double edge. When bending the edges in the folder or hatchet stake one is bent on the line R and the other on the line P.

A word about wiring. Care should be taken when notching the edges at the wire allowance to notch them as shown at J in diagram B, so that when formed up the ends of the wiring edges will butt sharp and make a clean, neat job. The soldered, riveted or grooved edges should come directly under the wire.

The Youngstown Iron, Sheet & Tube Company.

The Youngstown Iron, Sheet & Tube Company, now erecting sheet and tube mills at Youngstown, Ohio, have taken steps in the last few days that will call for the expenditure of a large amount of money and will very materially increase the capacity of this concern. They closed last week the purchase of Alice Furnace, of Pickands, Mather & Co., at Sharpsville, Pa., and contracted with Pickands, Mather & Co. for a ten years' supply of ore to run the furnace and also for a new stack to be built at Youngstown in connection with an open hearth steel plant, to have a daily capacity of 800 tons. The Youngstown Iron, Sheet & Tube Company are now negotiating for coking coal properties and will erect a large plant of ovens, probably of the beehive type, to supply their coke. The capital stock of the concern will be increased from \$2,000,000 to \$4,000,000, and it is possible \$1,000,000 of this will be in bonds. This matter will be fully decided upon at a meeting of the Board of Directors of the Youngstown Iron, Sheet & Tube Company, to be held at an early date. In Cleveland last week, George D. Wick, president of the concern, sold a large block of stock to interests connected with Pickands, Mather & Co. Mr. Wick will also recommend to the board the doubling in size of the present sheet mill, or perhaps the building of a 10-mill tin plate plant, and the erection of another large skelp mill and a pipe mill to roll up to 12 inches. The transactions already made and those under way will put the Youngstown Iron, Sheet & Tube Company in splendid condition, allowing them to make sheets and tubes from the ore up and entirely independent of the outside market. In fact, this concern will have one of the most modern plants in the country. It has very much outgrown the first plans when the company were organized.

The Tuscora Steel Company.

The new sheet mill plant of the Tuscora Steel Company, at Newcomerstown, Ohio, will soon be completed. The firm expect to start their black and galvanized sheet mills about January 15, and the galvanizing and roofing plant about February 15. The main building, containing four hot mills and the same number of cold mill, is 110 x 256 feet. The galvanizing department is 50 x 120 feet, and the corrugating and roofing department 62 x 240 feet. The first two buildings are finished and most of the machinery has been installed. Edward E. Erlkson of Pittsburgh is consulting engineer, and the plant was built under his supervision. The officers of the Tuscora Steel Company are Thomas Heckett, president; R. L. Shoemaker, treasurer, and A. T. Stone, secretary.

UNITED STATES CONSUL RAVENDAL of Beirut, Syria, says that successful efforts are being made to can Syrian fruit for export. During the past season some 5000 boxes of Tin Plate were imported from Europe for the manufacture of Cans, and the industry is growing so well that it is expected a considerably larger amount will be called for next year. The manager of the largest canning factory in Beirut, a French concern, the Consul says, is desirous of importing Tin Plates from the United States, and he suggests to any American manufacturers of Tin Plates who are interested that they communicate with Ch. Gailhac & Co., Société Française de Confection, Beirut, Syria.

FLASHINGS.

THE CANTON MACHINE & MFG. COMPANY, Canton, Ohio, are sending out a series of cards, 7 x 10 inches in size, illustrating and describing the new machines which they are now placing on the market. These include a 10-foot Combination Conductor Pipe and Eave Trough Forming Machine, a 10-foot Beading Machine for Eave Trough, a 10-foot Power Conductor Pipe Corrugating and Grooving Machine, a 10-foot Power Edging Machine for Conductor Pipe and a Slip Joint Cutting and Folding Machine.

It is reported that the American Can Company have decided upon the consolidation of a number of their factories, in order to reduce operating expenses and introduce more efficient modes of production, which can be accomplished through the consolidation of operations at a limited number of points favorably located in regard to supplies of raw material and transportation facilities. It is likely that the poorly located factories and those that have the least modern equipment will be dismantled and the machinery removed to other points where the buildings are owned, instead of leased by the company. In adopting this course the company will be following the policy of the other consolidations in metal lines. The company are understood to have very large orders on hand for next year's delivery. They made recently a sharp cut in the price of Tin Cans in order to meet the competition of independent manufacturers.

H. J. PRATT & Co., Springfield, Mass., have the contract for the Cornices and Metal Ceilings for a new block that is being erected in that city for Richard McKinney.

WILLIAM A. EDWARDS, a roofer, of Coxsackie, N. Y., met his death through an accident in falling from a building on which he was putting a Slate roof, on December 9. He was a member of a number of organizations and of the Second Reformed Church, where he had served as a member of the Consistory, superintendent of the Sunday school and a member of the church choir. He was also a member of the Scott Hook & Ladder Company. He was 55 years of age, and is survived by a wife and three children.

A. E. WEIANT, New Britain, Conn., has the contract for roofing the new block being erected by A. Bentz in that city.

F. H. SNEATH, Hartford, Conn., has the contract for putting Slate roofs on the Assembly Hall, at the Old People's Home, the Elks Building and a convex conservatory for Mrs. Mary Munsell, also on two large towers for the Health Underwear Company. He is also putting Snow Guards on the roof of the West Middle School, in Hartford.

THE 1902 calendar that A. W. Burdick & Co., tanners and slaters of 22 Hernando street, Memphis, Tenn., are sending out to their friends, and a copy of which has reached *The Metal Worker*, is an unusually handsome and artistic piece of work. The calendar is 14 x 18 inches in size, suitable for hanging on the wall. The border and monthly leaves are of dark green, with silver lettering, and form the frame for a fine reproduction in colors of the painting "Contentment," by Nonnenbrugh. This reminder of the donors will doubtless be greatly appreciated by all who receive it.

THE OHIO GALVANIZING & MFG. COMPANY's plant, at Niles, Ohio, will be ready to begin operations about January 15.

WE have received from W. J. Burton & Co., 164-166 West Larned street, Detroit, Mich., a set of samples of their special brands of Roofing Plates, which they are distributing to the trade. The samples are 3½ x 5 inches in size, attached together with a silk cord, and a card with each sample gives the description and weight per box, the weight of the coating and the sizes in which the Plates are made. The samples shown consist of Eastlake, Burton's Extra, Excelsior Hand Coated and Washington Old Style Terne Plates. The company advise us that they will be pleased to furnish these samples free of charge to all who apply for them.

THE CINCINNATI PUNCH & SHEAR COMPANY, Cincinnati, Ohio, are preparing to increase the capacity of their plant 20 per cent. by the addition of new tools. The company are shipping out a large number of their Tools and Machines in response to orders. Recently they have shipped two 10-foot Pack Shears to the Tuscora Steel Company, manufacturers of Sheets, at New Comerstown, Ohio, and two more Pack Shears for the National Enameling & Stamping Company of Granite City, Ill.

THE warehouse of the American Sheet Steel Company's plant, at Canal Dover, Ohio, was destroyed by fire recently, entailing a loss of \$10,000.

THE AMERICAN ROLLING MILL COMPANY of Chicago, Ill., have been incorporated by L. C. Stralght, Henry Huffield and J. C. Plrie with a capital stock of \$1,000,000.

THE 12-mill Sheet plant of the Sharon Sheet Steel Company, Sharon, Pa., is progressing. It is expected that it will be working on May 1.

It is reported that the National Roofing Association are considering a closer connection between the members. The project to concentrate their plants in or near Wheeling, W. Va., is said to be under contemplation.

FOLLANSBEE BROTHERS of Pittsburgh, Pa., dealers in Sheet Iron, Tin Plates, Roofing Material, &c., will erect a new three-story warehouse, 120 x 160 feet, at Second, Third and Short streets, Pittsburgh.

THE new plant of the Ashland Sheet Mill Company, Ashland, Ky., is rapidly progressing toward completion and will soon be put in operation.

I. PHILLIPS of the Welsh Tin and Sheet Mill Men's Association pointed out, in a recent report to that body, that in the first ten months of this year 14 per cent. more Tin Plate was shipped from Welsh works than in the same period of 1900, but that prices in 1900 were 7 shillings per ton higher than in 1901. The increase in shipments he attributes to the strike in this country. Considering the vicissitudes the Welsh Tin Plate trade has gone through, Mr. Phillips said it was marvelous to find it in its present position, and it was a proof that there has been a steady increase in the demand from other countries, as well as America. He added that the home consumption was about 40 per cent. more than it was ten years ago, so that they had the equivalent of 50 per cent. less shipments to America, or something like 1,200,000 boxes of Plates, which represented the production of 38 mills. The increase of 14 per cent., however, must have been entirely due to the increased domestic demand, as the export figures showed a slight decline.

SHIRLEY BROTHERS have opened a Tin shop at Mitchell, Ind., with Aura Brengle in charge.

FRIEDLEY & VOSHARDT, manufacturers of Sheet Metal Ornaments, Steel Ceilings, &c., 194 to 200 Mather street, Chicago, have just completed a Steel Ceiling for the Napoleon Hill Building, at Memphis, Tenn., requiring 500 squares, and are also finishing a Ceiling for the new Hunter Building in the same city, which will take 150 squares. The Ceiling in the Hunter Building is very elaborate in its design and is of the deep paneled pattern. The firm are establishing a high reputation for their workmanship, not only in their own locality, but also in distant parts of the country.

ARTHUR HUGHES has been appointed statistician for the Youngstown Iron, Sheet & Tube Company, at Youngstown, Ohio.

THE AMERICAN CAN COMPANY of New York City are enlarging their Empire works at Geneva, N. Y., by the erection of an addition, 100 x 150 feet, and a new power house, 40 x 50 feet, which will be equipped with a new Corliss engine and boiler of 100 horse-power capacity. The capacity of the plant will be increased to 75,000,000 Cans per year.

THE BELFAST CAN COMPANY, Belfast, N. Y., have been incorporated to manufacture Tin Cans and other Tin Specialties. They are now equipping a plant with new machinery. I. S. Hunt is president.

THE ALLEGHENY STEEL & IRON COMPANY, Park Building, Pittsburgh, with mills at Avenue, Pa., manufacturers of fine Sheet Steel, will add another furnace to their

open hearth steel department, and also increase their capacity for the manufacture of Sheets. The plant of this company was started up some time ago, and contains one 50-ton open hearth furnace, soaking pits, three-high Bar mills, four Sheet mills, one Tin mill, one jump mill and four sets of cold rolls. The product of the plant is 40 to 50 tons of Sheets per day.

THE YOUNGSTOWN IRON, SHEET & TUBE COMPANY, Youngstown, Ohio, are making new process Galvanized Sheets, at Niles, Ohio, in the works formerly operated by the New Process Galvanizing Company, which they purchased some time ago. Strong claims are made for the quality of Galvanized Sheets made under this process, and it is the intention of the company to furnish them from their Youngstown works in a short time.

PLANS are being prepared for the proposed new Tin Plate mill for the American Tin Plate Company, which is to be built in the Pittsburgh district, and which will adopt entirely new methods in the manufacture of Tin. While the officials will not say so, it has been intimated that the new plant will be a ten-mill one.

THE ALAN WOOD COMPANY, Conshohocken, Pa., placed an order with the Mesta Machine Company, Pittsburgh, Pa., for a pair of piston valve reversing engines, 50 x 60. These are to be direct connected and will be used for driving the new blooming mill that the Alan Wood Company will install. The contract for a pair of 40 x 60 reversing engines, geared 5 to 7, for operating their new blooming mill, has been placed with the Mesta Company by the La Belle Iron Works.

THE BOSTWICK STEEL LATH COMPANY of Niles, Ohio, held their directors' meeting last week and declared a 5 per cent. semiannual dividend. All departments were reported to be running full blast and the outlook most promising.

New Publications.

ERRORS IN SCIENCE TEACHING. By Professor C. Stuart Gager, Albany, N. Y. 73 pages; illustrated; size, 5 x 7 inches. C. W. Bardeen, publisher, Syracuse, N. Y.

This entertaining little book of Professor Gager's has been prepared, according to the introductory statement, for the purpose of pointing out some of the "false scientific statements and theories" published in modern text books, and which are generally received as absolute truth by students everywhere. The particular points dwelt upon in the work are the statements that "hot air tends to rise;" that "heat expands and cold air contracts," and that "water seeks its own level." Chapters are also devoted to cross pollination versus cross fertilization; how plants breathe; the course of ocean currents, and the cause of lunar tides. The work is written in a popular and attractive way, and will no doubt be read with interest, and possibly with surprise, by many students of natural science. It is illustrated by a number of diagrams and charts, and is written in such a clear and simple way as to be readily understood by the average school boy.

ELECTRIC GAS LIGHTING. By H. S. Norrie. 100 pages. 57 cuts. Size, 5 x 6½ inches. Published by Spon & Chamberlain, 12 Cortlandt street, New York, and E. & F. N. Spon, Limited, 125 Strand, London.

This book is issued with a view of conveying instruction as to the installation of electric gas lighting apparatus, including the jump spark and multiple system, for use in houses, churches, theaters, halls, schools, stores or any large buildings. It also contains directions for the care and selection of suitable batteries and in regard to wiring and repairs. The aim of the author is to enable any one possessing ordinary mechanical ability to construct much of the apparatus used for the purpose of lighting gas by electricity, or at least to successfully erect it and keep it in operation. The headings of the chapters convey a sufficient idea of the field aimed to be covered by the book. These are: "Multiple Gas Lighting Connections and Wiring;" "Primary Coils and Safety Devices;" "Lighting of Large Buildings," and "How to Select Batteries for Gas Lighting." The text is amply illustrated by engravings, and the book is gotten up in a very attractive style.

Business Conditions in Eastern New England.

We have received the following communication from a valued correspondent in Maine, which throws an interesting light upon existing business conditions in that part of the country:

In Eastern New England, and particularly in Maine and Eastern New Hampshire, a very hopeful feeling exists that 1902 will be the busiest and consequently most prosperous season that mechanical lines have seen for many a year. Maine responds slowly to good times, and after about two years of prosperity in the West, then always improvement slowly appears in this portion of the country. Now that good times have, apparently, reached their high in the West, we are just beginning in earnest to have our good time. It is the universal talk throughout the State of Maine that the present year has been the busiest, and, as a rule, the most prosperous year for a long time.

More buildings, especially high priced business blocks and residences, have been and are being erected than usual. This is rather a hard State in which to do much in the way of building in winter. Yet the present winter presents an exception in the unusual amount of such work that is being done. Most mechanical trades are unusually active for December; in fact, it is difficult to obtain men enough for the work required. The weather for the past month, however, has been very severe. Seldom do we have such large falls of snow and such continued cold weather; and, of course, this has somewhat retarded building operations. The general opinion is that 1902 promises even better than the present year. Architects and builders inform me that all signs point to a large amount of building for next year.

Low water in the rivers, thereby reducing the output of factories and mills, and in some cases closing, or partially closing, the same, has been the only cloud visible as likely to injure business for the next 12 months. But, thanks to the rains and thaws of the past ten days, that cloud has almost entirely disappeared.

Finally, a good year is due us. We always have, in time of prosperity, two to three years of good times, and 1901 has been one of them. We must have at least one more. Besides, in this State, we always have one good year after a panic strikes Wall street. As a panic has not yet struck Wall street, we, in this State, need not as yet furl our sails.

To Suppress the Chicago Smoke Nuisance.

Prevention of the smoke nuisance by thorough inspection of steam boilers and steam plants was aimed at in an ordinance submitted to the city Council of Chicago on the 16th inst. The measure was sent to the Council by Health Commissioner Reynolds and had been drawn up by the Municipal Art League. Dr. Reynolds wrote that the measure was in substantial accord with the recommendations of the Health Department, and he asked that it be referred to the corporation counsel for an opinion. The request was granted.

The ordinance provides for a new department for the inspection of steam boilers and steam plants, the chief inspector to be appointed by the Mayor for two years. The deputy inspector and smoke inspector of steam boilers and steam plants to be appointed by the Mayor upon the recommendation of the Civil Service Commission.

The ordinance combines present smoke inspection with the boiler inspector's office. In this way it is expected that smoke will be stopped before it reaches the air after a thorough inspection of plants.

The three officials are to form a Board of Inspectors, and this board will pass on all cases of violations. The fees will pay the salaries of the board and the assistants. The chief inspector is to be a man of practical experience, and the deputy must be a graduate of a reputable college of mechanical engineering, or have three years' practical experience, and neither must be interested financially in steam boilers.

The salaries of the members of the board are placed at \$3600 for the chief, \$3000 for the deputy and \$2400 for the smoke inspector. Elaborate provisions are made to prevent explosions, and boilers must be inspected before being placed in buildings.

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

EXPANSION TANK BOILS.

From S. J. S., Havre de Grace, Md.—Will you kindly assist me in overcoming the trouble with a hot water heating system which I have placed in four houses? My impression is that there is something wrong with the arrangement of the piping, from the fact that the water boils in the expansion tank, when the thermometer on parts of the heating system will not show a temperature above 200 degrees. The sketch herewith will show the arrangement, which is the same in all the houses. It will be noticed that at a point within a few feet of the furnace the expansion pipe is connected with the flow pipe. Would the trouble referred to be overcome if the expansion pipe was connected to the return pipe of the furnace, as shown by the dotted lines?

Answer.—Benefit will attend a change of the piping arrangement. The flow pipe should connect at the top of the radiator coil and the return pipe should be connected at the bottom. The expansion pipe may be connected as indicated by the dotted lines, but it would

Expansion Tank Boils.

be better to connect it with the flow pipe at the point where it connects with the radiator coil. Such connection would allow any air that might accumulate in the coil to escape, and at the same time would permit any steam that might be generated in the water heater to pass off. The connection between the expansion pipe and the flow pipe at the present time does not aid in the escape of air from the heating coil.

QUESTIONS ABOUT PLUMBING GOODS.

From Apache, Mammoth Hot Springs, Wyo.—Will *The Metal Worker* please inform me for what purpose the $\frac{1}{2}$ -inch plug is inserted in the bonnet of a gate valve? For what purpose is a Kittanning mixer used? Will a Mueller pressure regulator work on the water supply pipe in a building if placed in a vertical position?

Answer.—When large gate valves are subjected to a hydraulic test air naturally accumulates in the bonnet of the valve, and the $\frac{1}{2}$ -inch plug referred to is provided for the purpose of liberating the air. In some constructions the air may be allowed to escape around the stem of the valve, consequently the $\frac{1}{2}$ -inch plug is not found in all constructions of gate valves. The Kittanning mixer is a device used in connection with natural gas burners. The construction provides that the pressure of the gas issuing from the supply main draws in with it a certain amount of air, so that instead of burning with the ordinary red illuminating flame it burns with a blue flame of high temperature. The Mueller pressure regulator, being actuated by a spring, will work equally well whether placed in a vertical or a horizontal position.

SOLDERED STANDING JOINT FOR TIN ROOFING.

From Roofer.—I saw in *The Metal Worker* of November 23, under the head of "The Advantages of Tin Roofing," a reference to a patent soldered standing joint for tin roofing. Please let me know by whom it is made and how it is applied to the roof.

From S. H. K., Lufkin, Texas.—In *The Metal Worker* of November 23 is an article under the head of "Advantages of Tin Roofing," in which you refer to a patent soldered standing joint. Is this something new? Might I take the liberty, as a reader of *The Metal Worker*, to ask if you will inform me what this is? I should also like to get the name and address of the patentee of this style of roofing. I am doing a good deal of roofing and always like to keep up to date as nearly as possible.

Answer.—The device referred to in the article on "Advantages of Tin Roofing" is Reese's soldered standing joint, the patent on which is controlled by E. L. Parker & Co., Baltimore, Md. This device was illustrated and described in *The Metal Worker* of July 13, 1901. If our correspondents will communicate with the firm mentioned they will no doubt receive full particulars in regard to this method of roofing.

LIFT PUMPS WITH LONG SUCTION PIPES.

From F. F. T., Portlandville, N. Y.—Thinking it might help "C. R.," who inquires about pump work in *The Metal Worker* of December 7, I give the following description of a pump which I placed near this place. The spring from which the water was taken was 300 feet away from the pump and 29 feet below the level of the ground where water was desired. I used one of Gould's siphon well force pumps, with a $1\frac{1}{4}$ -inch suction pipe, without any air chamber, placing the pump in a pit so that the raise for the water to the pump was only about 19 feet. I used a check valve on the lower end of the suction pipe. Of course the pump worked very hard, but as power was used to run it it did its work well, pumping water for about 100 head of cattle and horses. I think if "C. R." places his pump as shown in the illustration given in the issue of December 7 it will work all right. If his cylinder is large an air chamber might be used with advantage. The pump I used was adapted for power, a belt running from a pulley on the pump to the shafting from which the power was supplied.

GALVANIZED IRON ROOFING ON THE SEA COAST.

From I. R., New York.—I have been on the roofs of a number of the large piers in this city, and to the correspondent "Roofer," who inquires in *The Metal Worker* of December 14 as to the durability of galvanized iron roofing in a salt atmosphere, I would say that owners of these buildings do not depend on the galvanizing alone for the protection of the iron. As soon as the gloss and grease have worn off from the galvanizing, through exposure to the weather, they are careful to coat it with a paint suitable for use on a zinc coated surface. The roofs of these piers are not only covered with galvanized iron, but in many instances the sides consist of corrugated galvanized iron siding fastened to a suitable frame work. This siding, as well as the roofs, is quite generally painted, at least on the outside, for there are some instances where the galvanizing alone has been depended upon to protect the iron on the inside. There seems to be little trouble from condensation and rust on the underside or inside of this covering of these more or less open piers. It is in protecting the outer surface that the most care is used. Galvanized roofing is far lighter and requires less expensive frame work to support it than slate, cement or any of the heavier materials. I am interested in this question, which is the reason why I make this contribution to the subject, and I hope that other roofers having experience in other cities along the coast will also give their views.

HEATING RADIATOR FROM STOVE.

From C. K., New York.—I should be glad to know if I can heat a radiator, located as shown in the sketch herewith, by means of a coil in stove having water circulating within the system. The radiator is to be on the same floor as the stove.

Answer.—In the accompanying sketch the dotted lines show the system of piping that will be needed for circulating the water. As our correspondent does not give the size of the room, the size of the radiator and the size of the pipe cannot be readily determined. If, as is probable, a radiator is used having 1 square foot of surface for each 30 cubic feet of space in the room, the heating will be satisfactory. Probably 1 inch-pipe will be large enough for the heating coil and the connections between it and the radiator. The size of the heating coil depends upon the size of the radiator used. If the coil is run around the fire chamber of the stove,

Heating Radiator from Stove.

so that the coal lies directly against it, it is probable that 1 square foot of surface in such a coil would take care of some 20 to 25 feet of surface in the radiator in the adjoining room. The size of the coil depends somewhat upon the size of the fire chamber in the stove and the manner in which the stove is run. The pipe to carry the hot water from the stove to the radiator should run nearly to the ceiling, and be carried over to a point above the radiator, where it should drop down and connect with the radiator, as shown. The return pipe may run along the floor until it comes to the stove, where it should rise and connect with the heating coil. If this is objectionable it may drop through the floor and run along the ceiling in the cellar. If this is done, however, the pipe should be covered, or a great deal of the heat of the water will be lost without benefit, and it will interfere with the heating of the room in which the radiator is located.

It will be necessary to provide an expansion tank, and if this is connected with the flow pipe near the ceiling, so that any air that would otherwise collect in the flow pipe may escape through the expansion tank, benefit will be derived. The expansion tank should be large enough to hold one-fifth as much water as is contained in the entire heating system. It may be placed near the ceiling of the room in which the stove is located, or may be set in a closet on the floor above, if that is more satisfactory and convenient.

MINERAL RODS AND MAGNETIC NEEDLES.

From M. C. R., Murillo, Ark.—I should like to know how the so-called mineral rods and magnetic needles are made, and should appreciate any information that you give me on this subject.

Answer.—The divining rod is an old device which originated with the magicians and alchemists of the Middle Ages. It has proved to be a fallacy and the fad of pretenders and sharps. The early construction consisted of a forked twig of hazel, apple or any fruit bearing tree. Later it was made with a small bottle of mercury fastened at the crotch of the twig and sometimes covered with fanciful devices. In its use the terminals of the branches were held in the hands in a horizontal line,

with the crotch or bottle end in a vertical position. Its dipping toward any object, or to the ground, is entirely due to the involuntary action of the muscles of the hands and arms; much after the same manner as with that other fad, the *planchette*. In using the rod, the hands are held in a strained and unnatural position, which renders it very difficult to hold the twig for any great length of time in the prescribed position without causing the muscles to twitch, and thus compel the branch to dip.

Bamboo rods with loadstone in one end and mercury in the other are used, and are fancied to dip from their balance to precious metals and water. A pendulum tipped with a vial filled with the kind of ore looked for and suspended by a string has been used, and fancied to vibrate in a line leading to an ore deposit. A plumb bob of hard rubber with some magnetic device in the bob and held by the hand has also been used for indicating subterranean water and minerals.

All such devices are gross frauds in their use, either by so-called experts or the misguided victims of superstition. The only reliable device for indicating the proximity of metallic ore is the dipping needle, which is only applicable in the search for ores of iron. No other metals, ores or objects have any effect upon its natural dip due to polar magnetic attraction. The dipping needle is much used in locating the trend of iron ore lodes, and has very correctly located hidden ore beds of iron only. The instrument consists of a delicately suspended magnetic needle, so balanced as to remain in a horizontal or nearly horizontal position when set in the direction of the meridian and normal to the polar direction. When moved toward, or over, an iron ore bed it immediately dips its north pole, and, if a free torsional needle, will swing in the direction of the main body of the ore. These needles with directions for their use are on sale by dealers in surveying and mining instruments.

WHAT IS THE BEST ROOF COVERING FOR ROUND HOUSES?

From J. R., Altoona, Pa.—In answer to the inquiry of "W. M." in *The Metal Worker* of December 14, I would say that the roof of a round house is no place to use metallic roofing, unless it be lead. I think there would be no difficulty with a wood framing, but the roof should be covered with slate, and nails of some composition or coated should be selected for fastening the slate on; otherwise, the action of the gases might eat the nails away until there would be nothing to hold the slates in position.

WANTS INFORMATION ABOUT A SUN MOTOR.

From G. K., Erie, Pa.—Several months ago we read in a daily paper an account of a sun motor, which had been set up and run in the State of California with success. The article in question, however, did not state by whom and where this motor was made. We should be glad if any of your readers who have this information would give it to us through the Letter Box.

HEATING MAINS IN OUTER WALLS.

From Y. F., Cranbrook, B. C.—I would like the opinion of some of the older steam and hot water fitters, through *The Metal Worker*, as to the advisability of running risers of a hot water heating system within an outside wall.

United States Consul Langer of Solingen, Germany, reports in regard to the trade school recently organized in that city, that it is obligatory for tradesmen, whether apprentices, assistants or factory laborers, to attend from four to six hours weekly until they reach the age of 17 years. The employer must pay into the city treasury the amount necessary for materials (which comes to about 72 cents annually) used by each person in his employ who is under obligation to attend the school. He is at liberty, however, to deduct such amount from the employees' wages. The Solingen trade school is supported, jointly, by the city and State.

TRADE REPORT.

MARKET SUMMARY.

Pig Tin is quiet and $\frac{1}{2}$ c. lower.

Copper is demoralized, with Lake Ingot $3\frac{3}{4}$ c. lower.

Pig Lead has declined $\frac{3}{8}$ c. per lb. and is dull.

Spelter is quiet and unchanged.

Hallett's Antimony is $\frac{1}{4}$ c. per lb. lower.

Nickel continues firm and unchanged.

Aluminum is active at former prices.

Tin Plates are quiet; American Cokes rule about 25c. per box lower.

Sheets are still in heavy demand and scarce supply; prices continue strong.

Sheet Copper is very quiet, and lower prices are looked for.

Pig Iron is very strong; Foundry Irons are about 25c. a ton higher; demand very heavy.

Hardware is rather less active, owing to advance of season, but demand is good and prices firm.

Scrap Copper and Brass are lower.

Scrap Lead is down $\frac{1}{2}$ c. a pound.

Galvanized Range Boiler prices have been withdrawn and higher prices are likely to be announced.

Plumbers' Brass Work is unchanged, but prices are likely to be readjusted owing to decline in Copper.

Solder is about $\frac{1}{2}$ c. per lb. lower.

Manufactured Brass and Copper prices have not yet been changed, but lower prices are looked for.

Wire Nails are somewhat irregular in price.

Cut Nails are in moderate demand at unchanged prices.

Wire prices are uneven.

Window Glass is dull and prices unsettled.

White Lead is in moderate demand; prices are not entirely even.

Linseed Oil is dull and 2c. to 3c. lower.

Spirits Turpentine is $\frac{1}{4}$ c. lower, but firm.

METAL MARKET.

NEW YORK, December 20, 1901.

Owing to the acute developments of the week in the cutting of prices of Copper and Lead and the weakness of Tin the entire metal market has been completely demoralized. Although purchasing has been made on a very conservative basis for some time now, consumers are more wary than ever. They are also considerably exercised over the cut in Lead, which, though a decline was expected, is much greater than looked for. Many consumers were caught with a pretty fair amount of stock going through their works. In disposing of the finished product considerable difficulty is expected.

Pig Tin.—Business has been exceedingly dull, with prices continuing on the downward grade. Arrivals are now coming in more freely and by the middle of next week will probably foot up about 2400 tons, which is considered ample to meet requirements at this time of the year. Further stocks afloat and expected to arrive in January will make up a sufficient supply for this month and next. Jobbers' prices on small lots of Pig Tin rule from $\frac{1}{2}$ c. to $\frac{3}{4}$ c. lower than a week ago—viz., at $25\frac{1}{2}$ c. to 26c. per lb.

Copper.—The market for Copper has been a scene of sensational surprises during the week. The first cut of $1\frac{3}{8}$ c., made at the end of last week, was followed on Wednesday by a further cut of similar amount, and on Thursday a third cut, amounting to 1c. per lb. was announced, making a total decline for the week of $3\frac{3}{4}$ c. for Lake Ingot for spot delivery. It is now believed in the trade that the base of 12c. per lb. for Lake Copper,

which was prophesied some time ago, is likely to be reached before the present downward movement stops. The reasons given by the principal selling interest for the radical decline in the price of Copper are the volume of competition and the falling off in both the domestic and the foreign demand. The consequence of the radical declines has been the total demoralization of the Copper market here. Naturally, under the circumstances, the volume of transactions was very light. In fact, no one for some time past has been buying more Copper than absolutely needed, in view of the general conviction which has prevailed in the trade for some time past that lower prices were certain to come, which conviction has been justified by the event. So far from any increase in the volume of business in consequence of the cut in Copper, consumers appear to be more reluctant to buy than ever, holding that now the decline has begun it is likely to proceed still further. Quite naturally, the outside producers are selling below the new quotation. Under the circumstances, prices are entirely nominal, but probably a fair quotation for small lots of Lake Ingot to-day would be $14\frac{3}{4}$ c. to 15c. The London market has declined sharply in correspondence with the market here.

Sheet Copper.—Naturally, under the unsettled conditions prevailing in the market for raw Copper, consumers are chary about buying Sheet Copper, the demand for which has shown a marked decline during the week under review. The last week or two of the year are normally dull ones in all Metal lines, but the falling off this week is above the average in extent. Users of Sheet Copper are buying nothing beyond what they absolutely need. While it is more than probable that the manufacturers will shortly announce a reduction in the price of Sheet Copper, no change has yet been made, and jobbers are still quoting small lots at the prices ruling for some time past. It is safe, however, to assume that lower prices for Sheet Copper, as for all Copper and Brass manufactures, will be announced in the near future.

Pig Lead.—An announcement by the American Smelting & Refining Company of a cut of $\frac{3}{8}$ c. in the price of Pig Lead on Tuesday startled the trade. While the decline was pretty generally expected in the trade no one looked for so wide a slash as was made, and it is said that many large consumers were caught. The cut followed the meeting of the American Smelting & Refining Company and the miners. An agreement was reached which represented about 80 per cent. of the principal warring interests. The miners agreed to close down their works whenever so ordered by the Smelting Company, and contracts were made on the basis of 3.50c. The demand for Lead is of small proportions and the market is dull and uninteresting. Jobbers have lowered their prices on small lots of American Pig to 4.45c. to $4\frac{1}{2}$ c. per lb.

Spelter.—While this metal is unchanged in price, the market has been to a considerable extent affected by the unsettled condition of other Metals and business is practically at a standstill. Stocks are very light and quotations are largely nominal. Good Western brands in small lots are still quoted by jobbers at $4\frac{5}{8}$ c. to $4\frac{3}{4}$ c. per lb. St. Louis reports indicate that the market for Spelter in that city for the past week has been less active, but prices are well held.

Antimony.—A cut of $\frac{1}{4}$ c. per lb. was made this week in the price of Hallett's Antimony, which now rules at $8\frac{1}{4}$ c. to $8\frac{3}{4}$ c. per lb. Cookson's is unchanged, being quoted in small parcels at $10\frac{1}{2}$ c. to 11c.

Nickel.—Is unchanged, continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—An active demand for Aluminum continues and prices remain at 37c. per lb. for small lots of No. 1 Ingot, guaranteed 99 per cent. pure, and 35c. per 100-lb. lots.

Tin Plates.—The situation in Tin Plates is without change of any kind, the market being dull and uninteresting. The only department that shows any particular life is the retail demand for small spot lots, which is surprisingly good for the season of the year. Prices in general are without change, but jobbers are quoting Coke Plates at slightly lower figures than those ruling a week ago. American Bessemer Coke, IC, 14 x 20, in small lots, at New York and corresponding points, now rule at about \$5.25 to \$5.50 per box. A further decline of 1½ pence in the price of Welsh Plates occurred this week.

Sheets.—There is still considerable difficulty in getting prompt deliveries of Sheets, notwithstanding that a number of the independent mills have started into operation. Business in both Black and Galvanized Sheets is still remarkably active, particularly for December and January shipments. All of the new mills have been able to sell up their product for 60 to 90 days. It is said, however, that some Sheet mills are soliciting orders for delivery in March and later. Most of the mills are taking contracts for Sheets at prices corresponding to those in force by the leading Sheet interest at the time the deliveries on these contracts are made. Retail prices continue very steady. No. 27 One Pass Cold Rolled Soft Steel Sheets are quoted by jobbers at 4c. to 4.05c. and Galvanized Sheets at 65 to 67½ per cent. off the list.

Chicago advices are as follows: The conditions previously reported are unchanged. The leading manufacturers are still much in arrears on deliveries, and the independent mills are unable to promise shipments inside of 60 days. The receipts, therefore, are falling under the requirements of the market, and this keeps prices firm. Mill shipments of No. 27 Black Sheets are quoted at 3.15c. to 3.40c., Chicago, and small lots from stock are selling at 3.50c. to 3.70c. Small lots of Galvanized are quoted at 70 to 70 and 2½.

Old Metals.—The sharp decline in Copper has caused weakness and a restriction of the demand for Scrap Copper and Brass, prices on which are lower, as also in Scrap Lead. Otherwise the market is quiet and without quotable change. Demand is of moderate proportions. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb. 13 c.
Light and Tinned Copper.....	per lb. 11¼c.
Heavy Brass.....	per lb. 8 c.
Light Brass.....	per lb. 6¾c.
Lead.....	per lb. 3¾c.
Tea Lead.....	per lb. 3¼c.
Zinc.....	per lb. 2¾c.
No. 1 Pewter.....	per lb. 16½c.
No. 2 Pewter.....	per lb. 8 c.
Tin Plate Scrap, per gross ton.....	\$6.00 to \$6.50
Wrought Iron Scrap, per gross ton.....	10.50 to 11.00
Heavy Cast Scrap, per gross ton.....	10.25 to 10.50
Stove Plate Scrap, per gross ton.....	8.00 to 8.25
Burnt Iron, per gross ton.....	5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—A good many consumers have now purchased well into next year, some of them up to August. The reports from the Lehigh Valley indicate that the floods have very seriously delayed work, and it looks as though there will be a good deal of trouble in the near future with the supply of blast furnace Anthracite. We quote: No. 1, \$16.35 to \$17.50; No. 2 X, \$15.75 to \$16; No. 2 Plain, \$15.25 to \$16; Tennessee and Alabama brands, No. 1 Foundry, \$16; No. 2 Foundry, \$15.25; No. 1 Soft, \$16; No. 2 Soft, \$15.25; No. 3 Foundry, \$14.75; No. 4 Foundry, \$14.25.

CHICAGO.—The deliveries for which furnace companies are willing to take orders are getting further off. It is now quite difficult to find either Northern or Southern furnaces prepared to assure shipments beginning earlier than next April, for the standard grades of Iron are all well sold up. The furnace companies are still hampered greatly by the scarcity of Coke and the lack of cars, and it is believed that it will take until April to enable them to catch up, even if no additional business is booked. The week has been characterized by some heavy transactions, running in some cases up to several thousand tons. Southern Iron was mainly bought, although the share falling to the local furnaces was by no means small. A sharp demand is noted for spot

Iron. A great many foundries are buying from hand to mouth and need prompt deliveries. A disposition is noted to higher prices on Southern Iron, as some companies have made advances of from 25c. to 50c. This movement, however, is not general. We quote as follows:

Lake Superior Charcoal.....	\$18.50 to \$19.25
Local Coke Foundry, No. 1.....	16.00 to 16.50
Local Coke Foundry, No. 2.....	15.50 to 16.00
Local Coke Foundry, No. 3.....	15.00 to 15.50
Local Scotch, No. 1.....	16.00 to 16.50
Ohio Strong Softeners, No. 1.....	17.60 to 17.85
Southern Silvery, according to Silicon.....	16.15 to 16.40
Southern Coke, No. 1.....	15.65 to 16.15
Southern Coke, No. 2.....	15.15 to 15.65
Southern Coke, No. 3.....	14.65 to 15.15
Southern Coke, No. 1 Soft.....	15.65 to 16.15
Southern Coke, No. 2 Soft.....	15.15 to 15.65

PHILADELPHIA.—About the only thing to be said in connection with Pig Iron is that there is practically no Iron for sale for early shipment. Everything is closely sold up, and, more than that, there is a great deal of Iron due for delivery this month that cannot be got out, owing to restricted transportation facilities. Very little new business is now being done. Sellers are more interested in cleaning up old contracts than in making new ones. The general impression is that prices during the first half of the coming year will not be materially different to what they are to-day—that is, somewhere around \$16 for No. 2 X Foundry. Prices at the present time are more or less nominal, but the extreme figures both ways would be about as follows for Philadelphia and nearby points: No. 1 X Foundry, \$16.25 to \$16.50; No. 2 X Foundry, \$15.75 to \$16.25; No. 2 Plain, \$15.35 to \$15.65.

PITTSBURGH.—The Bessemer Iron market is extremely active and very strong. The car situation seems to be worse than at any time since the car shortage started and quite a few furnaces in this district are banked, being unable to get Coke. This is adding to the scarcity of Pig Iron and it looks as though prices might be higher. Foundry Iron is active and some consumers have practically covered their entire requirements for the first half of next year. We quote Bessemer Iron at \$16.50 to \$16.75; No. 1 Foundry, \$16.50 to \$16.75, and No. 2 Foundry, \$16 to \$16.25, all f.o.b. Pittsburgh.

CINCINNATI.—The strength of the Pig Iron market was never better evidenced than by the remarkable activity which developed during the past week. Not only was there a pretty general clearing out of all standard Irons for the next quarter's delivery, but odd lots, off grade assortments, and in fact everything weighing 16 ounces to the pound and called Pig Iron has been sold. At this writing there is a good tonnage in the way of inquiries which have gone the rounds and could not be filled. The selling prices have not been changed from the figures given a week ago, but it is a foregone conclusion that a rise of 50 cents will be called for within the next few days. The complaint regarding car shortage is as loud as it has been, and there is no prospect of any immediate betterment. We quote, f.o.b. Cincinnati:

Southern Coke, No. 1.....	to \$15.00
Southern Coke, No. 2.....	to 14.25
Southern Coke, No. 3.....	to 13.75
Southern Coke, No. 4.....	to 13.25
Southern Coke, No. 1 Soft.....	to 15.00
Southern Coke, No. 2 Soft.....	to 14.25
Southern Coke, Gray Forge.....	to 13.25
Southern Coke, Mottled.....	to 13.25
Ohio Silvery, No. 1.....	\$15.60 to 16.10
Ohio Silvery, No. 2.....	15.10 to 15.60
Lake Superior Coke, No. 1.....	to 16.60
Lake Superior Coke, No. 2.....	to 16.10
Lake Superior Coke, No. 3.....	to 15.60

ST. LOUIS.—A considerable increase in activity in the Pig Iron market was noted in the past week. The volume of inquiries and sales is pronounced to be very satisfactory. Some substantial orders have been booked, including several sales of 1000 tons, to which can be added numerous smaller requirements. Most of the latter are for immediate delivery, while the larger ones are to come during the first three months of the new year. Rumors of advances to come in freight rates are still heard, but nothing definite can be announced. We quote as follows for cash, f.o.b. St. Louis:

Southern, No. 1 Foundry.....	\$15.50 to \$15.75
Southern, No. 2 Foundry.....	14.75 to 15.00
Southern, No. 3 Foundry.....	14.25 to 14.50
Southern, No. 4 Foundry.....	13.75 to 14.00
No. 1 Soft.....	15.25 to 15.50
No. 2 Soft.....	14.75 to 15.25

CHICAGO REPORT.

Scrap Iron and Steel.—The demand is a little better, as dealers are buying more freely to fill old contracts or with the belief that prices may shortly be higher. We quote dealers' buying prices for carload lots, Chicago delivery, as follows:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	8.00 to 8.50
Burnt Iron and Grate Bars.....	5.50 to 6.00
Sheet Iron and Hoops.....	6.00 to 7.00
Plow Steel.....	... to 10.00
Breaking Stock.....	9.00 to 10.00
No. 2, such as Shovels, Hoes, &c.....	... to 7.00
Old Boilers—whole (Iron).....	6.50 to 7.00
Old Boilers (Iron) cut in single Sheets and Rings.....	10.00 to 11.00
Old Gas Pipe and Boiler Tubes.....	10.50 to 11.00
Cast Borings.....	4.50 to 5.00
Turnings	9.50 to 10.00
Horseshoes	12.00 to

Old Metals.—The drop in Ingot Copper has caused prices of Old Metals to be reduced. Consumers are buying sparingly. Dealers quote buying prices on small lots as follows:

	Per lb.
Copper Wire and Heavy.....	13 c.
Copper Bottoms.....	12 c.
Copper Clips.....	13 c.
Red Brass.....	13 c.
Yellow Brass.....	9 c.
Red Brass Borings.....	10 c.
Yellow Brass Borings.....	8 c.
Light Brass.....	7½c.
Pipe Lead.....	3.90c.
Tea Lead	3 c.
Zinc	3 c.
Tin Foil	22 c.
Pewter, No. 1.....	16 c.
Pewter, No. 2	15 c.

Old Rubber.—Trade shows no improvement. We quote as follows:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7 c.
Rubber Car Springs.....	5½c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	6¾c.
Black Rubber.....	4¼c.
White Rubber.....	8½c.

Rags.—Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at 75c. to 85c. per 100 lbs. in any quantity.

Anthracite Coal.—The demand is very good, with Chestnut in scanty supply, caused by the shortage of cars. Prices are unchanged, as follows:

	Grate.	Egg and Stove.
Chicago	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

THE HARDWARE TRADE.

Business continues to give more definite indications of the near approach of the holidays and of the end of the year. Many travelers are already at home, and on this account, as well as because it is a time when, in anticipation of the annual inventory, purchases are restricted as much as possible, less effort is being made by manufacturers to secure orders. The volume of business thus shows a falling off. Notwithstanding these influences, which tend to restrain the movement of trade, there is a good deal doing. The most obvious and urgent business is in sorting up orders to meet immediate requirements. Of such demands there are many, as retailers' stocks generally have been quickly depleted as a result of the good business conditions which have so generally prevailed. It is found that even with a liberal buying vacant places on the shelves and in the warehouses are apt to develop. The prosperity which exists has prepared the way for an exceptionally good holiday trade, and large stocks of suitable goods have been laid in. The cold weather, which has visited many parts of the country, stimulates the calls for winter goods. Some of these are in somewhat inadequate supply. These influences are causing merchants to make urgent orders upon jobbers and manufacturers, and in spite of the season trade is thus unusually active. In the promising condition of trade and the hopeful feeling that prevails liberal purchases are also being made by jobbers and the larger re-

tailers for next year's requirements. The manufacturers are generally taking a much stronger and more independent position with their customers than has been usual until the last year or two. Guarantees are given less recklessly and prices are adhered to more firmly. There is, too, a determination to refuse to accept blanket orders or to make contracts all the advantages of which are on the side of the buyer. The difficulty of obtaining raw material is still felt in many lines, and this, with the strength of the Iron market, gives a firm tone to prices generally. The few lines which are under suspicion have apparently little influence on the market as a whole. The break in Copper has not yet had much influence on the market in manufactured goods, owing to the fact that it was in a good measure anticipated. Collections are in general satisfactory, and the whole trade is evidently in excellent condition.

NOTES ON PRICES

Galvanized Range Boilers.—It was intimated this week that after January 1 an advance would be made in the price of Galvanized Kitchen Range Boilers. The Range Boiler Association, at the present time, is in a very satisfactory condition. Only one concern (which makes a patented Boiler) is outside of the association. According to reports which have been made to the association regarding the output and sale of the different manufacturers, there is a feeling that the time is ripe for better prices. We understand that the manufacturers of Steel Plates have insisted that all specifications now in must be completed and shipped by January 1, and all orders which they hold, on which they do not receive specifications, will be cancelled on that date. They are also said to have informed their patrons that prices for Steel Plates are likely to be higher after January 1. If a change in the price of Steel Plates takes place, as anticipated, there will be a sympathetic advance in the price of Boilers.

Plumbers' Brass Work.—The market for Plumbers' Brass Work remains unchanged. Stocks in the hands of the jobbers are as low as they possibly can get them. Owing to the present unsettled condition of the Copper market, persons having large orders to place are chary of placing them. The recent reduction in the price of Copper will necessitate the recasting of costs in all of the shops of the Brass manufacturers. There will be a meeting of the Brass Association in the early part of January, at which we understand several items are likely to undergo a radical change in price. The present selling price to the jobber on several lines of Brass Work is regarded as entirely too high, and the high price made by the manufacturers seems to be having an entirely different effect from what was anticipated by them.

Solder.—The further decline in the price of Pig Tin has been accompanied by lower prices for Solder. Half and Half, guaranteed in small lots, is now quoted by jobbers at 17 to 17½ cents, and No. 1 at 14½ to 15¾ cents per lb.

Copper and Brass Goods.—The decline in Ingot Copper, as referred to elsewhere, has naturally had more or less influence on goods into which this metal enters as a material, but has had as yet comparatively little effect on current prices. The trade have been watching the course of things and keeping in close touch with the Copper market, so that they have been prepared for the present condition of things. What has happened has thus, in large measure, been provided for, and in Copper products generally there has been little change in the market. The general consensus of opinion is that for the present, and probably for the rest of the year, there will be no important changes in prices. A meeting of the manufacturers comprising the American Brass Association was held Tuesday, December 17, at which it was determined to make no reduction in goods manufactured by them. As the interests dominating this association practically control those of the American Sheet Copper Association, it is confidently predicted by responsible sources that no change in price in Sheet Copper will be made in the near future. The same process of reasoning applies to the Seamless Brass and Copper Tube As-

sociation, who met December 17 and made no changes in price. While radical changes in Raw Copper may alter the present status, it is believed that no radical reductions will be made in manufactured Copper and Brass this year. What may occur in the middle or latter part of January is another matter. One argument of manufacturers of Copper and Brass is that with stocks of material on hand at the old price a sufficient period should elapse to work it off at current rates, especially as the domestic demand warrants it. The present price of Bare Electrolytic Copper Wire at mill is 16¼ cents per pound, base; Insulated Weather Proof Wire, 15¼ to 16 cents at mill. Sheet Brass, Brass Rods, Brazed Tubing and Brass Wire are still quoted at the old prices, a good reason for which is the relatively low prices at which Brass Goods have been sold for some time.

Wire Nails.—There is no noticeable change in the condition of the Wire Nail market. Prices have reached a level below which there appears to be little desire on the part of makers to go. The strength of Billets, which are high in price and hard to obtain, naturally has somewhat of a restraining influence upon the Nail market. Irregularity in quotations continues, and prices made depend largely upon the location from which Nails are ordered. The demand for Wire Nails in the New York market has fallen off somewhat during the week. Shipments from some mills have been delayed as the result of the recent severe rains. Most of the jobbers at this point have comparatively light stocks, and will be inconvenienced if the delay in receiving Nails is prolonged. Small lots from store rule at \$2.35 to \$2.40 per keg.

Cut Nails.—Cut Nails continue to be ordered in about the usual proportions. The representatives of mills are adhering to the price of \$2.25 per keg for Nails from store. Jobbers are asking the same prices generally, although in some instances they are selling at 2 cents below these figures.

Wire.—The Wire mills have pretty well caught up with their orders and are now making reasonably prompt deliveries. The demand from manufacturers of Wire products is large, but there is a good deal of unevenness in prices. Jobbers quote Plain Wire in small lots, New York, at about 2.55 cents and Galvanized at 2.95 cents.

Window Glass.—As far as can be learned, there is little indication of headway being made toward bringing the outside Window Glass manufacturers into a price agreement with the combine. The market is unsettled, especially in the West, as the result of low prices made by factories outside the combine. The Jobbers' Association quotation on less than carload lots from store, on both double and single strength, over the entire country is 90 per cent. discount.

White Lead.—It is reported that a meeting will soon be held by the Crushers' Committee to try and harmonize the different views now existing, and, if possible, to put the prices of Lead products upon a more even basis than has recently characterized the market. The demand for White Lead in oil is only moderate, and the quotations are unchanged, small lots from store ruling at 7 to 7¼ cents per pound. These quotations are not infrequently shaded ¼ cent or so, however.

Linseed Oil.—Some of the city crushers have reduced the price of Raw Linseed Oil in large lots 3 cents per gallon, and others are still holding to former prices. The decline is the result of a dull market, and has taken place in face of an advancing Seed market. City Raw Oil, in small lots, is quoted at about 54 to 55 cents per gallon. The demand is confined almost wholly to small lots.

Spirits Turpentine.—There is a fair demand for Turpentine at this point at ¼ cent less than the figures quoted last week. The Southern market is reported strong as the result of good buying for export. The retail price of Turpentine is now 38¾ to 39¼ cents per gallon.

A CONSOLIDATION has been effected between the H. W. Johns Mfg. Company of New York and the Manville Covering Company of Milwaukee, Wis., which concerns are among the largest manufacturers of Asbestos Goods

in the world. The new concern will be known as the H. W. Johns-Manville Company of New York City. They have been incorporated with a capital stock of \$3,000,000, of which \$500,000 is in 7 per cent. accumulative preferred shares, and \$2,500,000 in common stock. The incorporators are: T. E. Wing, H. F. Ballantyne, G. W. Davenport, Robert Dickson, H. M. Wolfe, E. T. Roos and H. S. Burroughs of New York, and W. W. Orr, J. W. Fair and M. B. Fair of Scarsdale, N. Y. The consolidated company will establish headquarters in New York City, with branch offices in Chicago, Milwaukee, St. Louis, Philadelphia, Boston and other cities.

THE GLOBE MACHINE & STAMPING COMPANY of Cleveland, Ohio, have commenced operations in new quarters at 970-972 Hamilton street, that city, where they have treble their former floor space. They have recently purchased several new tools and are contemplating buying additional machinery. They manufacture special Tools, Dies, Stamped Metal Work, Hardware Specialties and Small Machinery.

**TINSMITHS
HELPER and
PATTERN
BOOK**

WITH USEFUL RULES,
DIAGRAMS and TABLES
= By H. K. VosBurgh =
NEW AND IMPROVED EDITION

A USEFUL handbook for tinsmiths and other mechanics, treating simple problems in pattern cutting, such as are of daily occurrence in the shop. An elementary manual for the young tinsmiths. A handy reference for all sheet metal workers.

120 Pages
53 Figures

An Invaluable \$1.00
Pocket Companion . .

**Section 1 ~ Pages 1-66
Diagrams and Patterns**

Demonstrates in a simple way, and by means of illustrations and descriptive text, about 50 examples of sheet metal pattern work, such as the method of cutting can breasts, flared tinware, scale scoops, oval boiler covers, lips for measures, elbow patterns, &c.

**Section 2 ~ Pages 69-88
Epitome of Mensuration**

Compiled with regard to the requirements of the tinner, describing how to find the area of a circle, the circumference of a circle, the contents of a sphere, a cylinder, a cone, and other information relating to the work of a tinsmith.

**Section 3 ~ Pages 89-120
Tables, Rules, Recipes**

Gives tables of the weights of sheet metals, including the weight of black sheet iron, sheet lead, and galvanized iron sheets with their dimensions; the weight of lead pipe per foot; the weights of tin plates, sheet copper and sheet zinc. Several pages are devoted to tables giving the areas and circumferences of circles, the capacity of cans, the number of barrels in cisterns and tanks, sizes of tinware in form of frustum of a cone, &c., and practical receipts, including mixtures for solders of different kinds, soldering fluxes, and various cements.

Domestic Electrical Work.

Concise and Practical Explanations for Plumbers, Tinnors and Hardware Dealers on How to Wire Buildings for Bells, Alarms, Annunciators, and for Gas Lighting from Batteries.

Illustrated with Twenty-two Diagrams.

By **WILLIAM A. WITTBECKER.**

Price in Paper, 25 Cents.

Price in Cloth, 50 Cents.

The growing demand for simple electrical apparatus in dwelling houses, offices and workshops, and the need of plain instructions whereby any person without a previous knowledge of electricity may be enabled to undertake their successful installation, has prompted the publication of this little book. It is not intended for the amateur who seeks for nothing but experimental work, neither is it expected to enlighten the expert electrician; but to the person who is seeking for information that will assist him in increasing his daily earnings this little volume is addressed. The information given is above all else practical, and with a close observance of the directions laid down any one without the slightest knowledge of electricity should be able to do the work described.

CONTENTS.

- Chapter I.—Simple Bell Circuit.
- Chapter II.—Multiple Bell Circuit.
- Chapter III.—Various Circuits.
- Chapter IV.—Fire Alarms.
- Chapter V.—Annunciators and Alarms.
- Chapter VI.—Burglar Alarms.
- Chapter VII.—Automatic Fire Alarms.
- Chapter VIII.—Electric Gas Lighting.
- Chapter IX.—Running Wires in Finished Buildings.

A UNIVERSAL REMEDY FOR LEAKY ROOFS.

The valuable qualities of a good roofing cement are firm adhesiveness and elasticity. These qualities the American Seal Builders' and Roofers' Elastic Oil Cement possesses. It will adhere firmly to Slate or Metal and will not crack or crumble. It is especially recommended for repairing leaks around chimneys, dormer windows, skylights, scuttles, firewalls and any place that requires fixing on a roof, either Slate, Tin or Shingle.

This Cement will answer to repair a roof when Solder cannot be used.

PUT UP In Barrels, about 800 lbs. In Tubs, about 112 lbs. In 25 and 50 lb. Pails. In 5, 10 and 15 lb. Pails.

Galvanizing and Tinning.

A Practical Treatise on Coating with Tin and Zinc, with a Special Chapter on Tinning Gray Iron Castings. By W. T. Flanders. Size 5½ x 8 inches. 98 pages, 40 illustrations. Cloth bound. Price \$2.00.

The author of this work has made a specialty of galvanizing and tinning, and has been employed to erect plants in various parts of the country, also to instruct the owners, so that, in all instances, they have been able to operate them successfully. The subject of galvanizing is, therefore, treated from the standpoint of an expert and in a practical manner. The selection of materials and apparatus for erecting plants of large and small capacity is treated, together with instructions for their equipment and accompanied by many illustrations of the plants and of the tools and appliances. Plain directions are given for the preparatory treatment of metals and articles to be coated, and every detail which is of importance in successfully applying to metals a secure and attractive coating is described. The tinning of articles is treated in the same practical manner. The difficulties found by many who have attempted to tin malleable and gray iron castings are explained and methods for doing the work made simple.

CONTENTS.

Galvanizing.

Locating a Plant and Selecting a Kettle.

CHRISTMAS GREETING

A GOOD, old-fashioned Merry Christmas to every man who has anything to do with sheet iron—we feel as though we knew every one of you.

We would like to shake your strong right hand and thank you personally for any share of your trade that came our way the past year. We remember and appreciate it. To be sure you got the best that was to be had for the money and we tried our best to please and treat you right. In 1902 we will do still better. We promise you that, trusting to your good will, good judgment and good business practices for a continued generous support. We again wish you most heartily the compliments of the season and gently remind you that we are always ready to serve you to the best of our ability.

OLIVER POCKOCK,

1073-1075 Clark St., Cincinnati, O.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting as applied to all branches of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection of 218 problems and an elaborate explanation of the principles of pattern cutting, including Triangulation.

It embodies the problems of the former Metal Worker Pattern Book, all of which have been revised, and many of which have been entirely rewritten and solved by more approved methods. To these have been added 75 new problems and much other new material and explanatory matter, making this work a model of completeness in every respect.

ARRANGEMENT.

In point of arrangement the new work far surpasses the former one in that the problems are classified under three different heads, and simply indexed, and also that by means of a table of contents any required department of the work can be easily found.

CONTENTS.

While Chapter VI, comprising the greater part of the work, is devoted to the solution of problems, the five preceding chapters thoroughly explain the principles of pattern cutting, and place the student in possession of the preliminary information necessary to a thorough understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

THE ELECTRIC CITY GUTTER FORMER.

The Electric City Gutter Former can be bought for 50 per cent. less than other machines intended for the same purpose. This machine will do everything that can be accomplished by any other gutter former. No other machine can do better work. No other machine can do quicker work.

The principle of this machine is entirely different from any other. It is more practical. Both the bead and the gutter are formed in one continuous operation. You do not waste any time in hard work in getting the body of the gutter in proper shape. Every operation is mechanical. Each length of gutter is formed exactly alike. No other machine is as practical in its operation. No other machine will give as much satisfaction. The low price is very attractive. The machine will perfectly demonstrate our claims. Ask us about it. We gladly furnish information and price on request.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows,

ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No. 12 gauge, cut wire or bar-steel 1/4 inch thick, cut off and mitre angle iron 1/2 inch thick, and do it perfectly.

PRICE, - - \$35.00.

Excelsior Point No. 5.—PLENTY OF HOT WATER.

The reservoir boiler of the Excelsior Range being elevated horizontally over the top of the upper closet, the circulation between the waterback and the boiler is very rapid. An abundance of hot water is thereby assured. All sizes of the Excelsior are arranged also for use with an upright boiler for those who prefer that arrangement. If your range is the Excelsior you may depend upon an abundance of hot water for bath and kitchen.

HOT BLAST SMOKE CONSUMER

Warm Air Furnace

FOR SOFT COAL.

A heavy, substantial, all cast iron and strictly high grade Heater; especially constructed for soft coal fuel.

THE HOT AIR BLAST APPLIANCE

Is so formed that the distribution of the hot air to the combustion chamber is equally divided at three points: at the back and on each side. This appliance embodies the important advantage of a hot air blast and also the very vital point of a durable construction. This question of durability of a hot blast appliance for soft coal fuel is one that has caused much annoyance and expense, and in this construction we have carefully provided for this important point. It is not a part of the combustion dome or fire-pot, insuring equal expansion and contraction. The air is discharged into the combustion chamber directly over the surface of the fire and at a very high temperature, yet the construction is such that the combustion does not come in direct contact with it; the parts are allowed to expand and contract equally.

The **BOYNTON FURNACE CO.,**
NEW YORK, CHICAGO.

READ OUR OFFERINGS.

Special Advantages Over All Other Heaters.

OUR HEATERS are only 4 ft. 3 in. high, giving excellent elevation for Hot Air Pipes.

OUR HEATERS ARE ALL CAST IRON, no repairing of sheet iron drums necessary every few years.

OUR MANIFOLD TUBES are steel, $\frac{1}{8}$ inch thick, and will wear for a lifetime.

OUR HEATERS are supplied with the most modern grates, perfect dumping and shaking. Each bar can be separately replaced.

OUR HEATERS are so arranged that they can be perfectly cleaned by any one, and in a few moments.

Equally Efficient with Hard or Soft Coal.

Our Heaters save the heat others waste up the chimney and send it through the house, therefore reduce coal bills.

QUICK MEAL

Gasoline Stoves.

THE success of "Quick Meal" Evaporating Stoves is unquestioned. They have stood the test of years. Their Burners are perfect, simple and durable, easy to regulate and easy to keep clean. The assortment is larger than the largest made. Their design is now prettier than ever and their finish unsurpassed. There never was a Gasoline Stove prettier, better or simpler than the "Quick Meal" Evaporator. Their enormous and ever increasing sale tells the tale.

Correspondence solicited in unrepresented territory.

P. S.—"Quick Meal" Steel Range sales are double of what they were a year ago. Do you sell them? If not, you are not selling the Best.

Our furnaces and specialties are great levers for pushing business your way. Exclusive agencies given.

WIRETON HEATING CO.,

Main Office and Works, Blue Island, Ill. Chicago Office, 40 Dearborn St.

A Marvelous Seller.
Will automatically turn on the draft of any furnace, steam or hot water boiler

If you have three (or a dozen) first-class ranges from as many different manufacturers, look them over if you don't already know how they are built. Probably one will have a sheet flue on the flue end, with an uptake flue on the back of the oven. This construction heats all of four sides and a part of the fifth. The others have the old reliable divided flue on the flue end, the division (or the flue strip) extending under the bottom oven plate, to within 6, 7, or 8 inches of the front oven plate, the gases passing around this back to the right half of the flue end. This construction heats only four sides of the oven. The "HOME WINTHROP" heats ALL OF FIVE SIDES of the oven; the divided main flue in on the back of the oven, with an auxiliary sheet flue on the flue end. The top, bottom, fire end and back of the oven are heated more evenly and with less fuel than is possible with any other construction.

	8 x 20 or 9 x 20
The Oven measures.....	20 x 20 x 12½ inches.
Fire Box INSIDE Coal Linings.....	17⅛ x 7¼ x 7⅜ inches.
Ash Pit.....	17⅜ x 18 x 4½ inches.
Fire Box for Wood.....	26 x 7¼ x 7¼ inches.

The Water Front is 19 inches long, 7¼ inches deep. The dust flue takes ALL the dust away, even if the draft slide is open when you shake the grate. The Ash Pan covers ALL of the under surface of the grate. If you are selling some other good range, you can claim it will do a stated amount of work with less fuel than any other range, but you can't show any good reason for your claim. If you sell the "HOME WINTHROP" you can show why it will do the work with one-third less fuel than any other range, and your customer, after trial, will substantiate your claim at any time you may have occasion to ask him to do so.

DIGHTON FURNACE CO., TAUNTON, MASS.

Burn Hard or Soft Coal, or Coke. Large Doors.

Some Ripe Experience

Has come to us through watching the doings of dealers throughout the United States.

We find that the dealer who sells cheap furnaces not only loses ground in the furnace business but also has a falling off in his other lines.

On the other hand, we can say that the man who sells a good furnace and charges enough to do a good job will, in a few years, be the leading furnace man in his town and at the same time build up his other business.

The *American Furnace* is made for the better class of trade; is durable, clean and economical in fuel.

ABOUT ESTIMATE BOOKS

For Plumbers and
Heating Men

Your Contract and Estimate Record Book for Plumbers is one of the best books that ever came into our house and we would not be without it for three times the amount it cost. We can figure without omitting anything with accuracy at a very short time. We think that every plumber should not be without this valuable book.

W. C. BENNETT & CO., Haverhill, Mass.

We have used an estimate book for three years and could not do without one. Would say that yours is far superior to any yet used and can cheerfully recommend it.

W. R. PARK & SON, Taunton, Mass.

A great advantage. Prevents the leaving out of small items, which amounts to more than the cost of the book in a very short time.

CHAS. W. COOMBS, Lawrence, Mass.

Your Contract and Estimate Record Book has been of great use to me in both the saving of money and labor, and I would highly recommend it to any or all master plumbers.

THOMAS P. DOHERTY, Taunton, Mass.

These testimonials are a few of many, and indicate both that a well arranged estimate book, which provides complete lists of items to be figured upon, is a time, labor and money saver, and that the "CONTRACT AND ESTIMATE RECORD BOOKS" come up to this requirement.

THE EDITIONS ARE AS FOLLOWS:

CONTRACT AND ESTIMATE RECORD BOOK FOR PLUMBERS

OFFICE EDITION.

200 Pages. Arranged for 100 Estimates.
Size 8 x 11 inches. Cloth bound, \$1.50
500 Pages. Arranged for 250 Estimates.
Size 8 x 11 inches. Cloth bound, \$2.50

POCKET EDITION.

200 Pages. Arranged for 50 Estimates.
Size 3½ x 8 in. (oblong). Flexible cloth
binding, \$0.50

CONTRACT AND ESTIMATE RECORD BOOK FOR STEAM AND HOT WATER HEATING

200 Pages. Arranged for 100 Estimates.
7 x 12 inches. Cloth bound, \$1.50

NOTE. The omission of one item in an estimate on a plumbing or heating job might result in the loss of all profit. These books provide a reliable, accurate, business-like record, and a sure means of avoiding loss due to mistakes and omissions.

Sent prepaid on receipt of price.

SAVE HALF

The expense of installing closets by getting

Zero Anti-Freezing Valves.

They can be put in with half the time and half the labor because they do not require a pit or vault.

They are simple and durable in construction—made without screws, springs or pins.

Zero Valve & Brass Mfg. Co.,
296 Seneca St., Buffalo, N. Y.

This edition contains besides the two original articles on joint wiping, by experts, a selection of letters and articles on various important phases of the subject. These include the following:

- Joint Wiping on Copper Pipe.
- Wipe Joints on Brass and Iron.
- Wiping Joints on Tin Pipe.
- Wipe Joint on Lead and Iron Pipe.
- To Make Tight Joints.
- Froze the Pipe to Wipe a Joint.
- Wiping Joints Without a Furnace.
- The Effect of a Jar on a Hot Wiped Joint.
- What Caused the Joint to Break?
- Strength of Joints in Lead Pipe
- Good Wiping Solder.
- Durability of Coarse Solder.
- Plumbers' Paste.
- Cleaning Solder.
- What Breaks Wiped Joints?
- Hard Solder to Resist Ammonia.

The first article in the book is written by a practical plumber, and is illustrated from photographs representing the hands and tools when wiping joints in various positions. The second, by an expert joint wiper, is also illustrated from photographs and will prove of great assistance to learners. Ample instructions are given on preparing the pipes previous to wiping the joints, with full descriptions of all tools and appliances used. The pamphlet, in short, gives all the assistance that description of the work can furnish and is the most practical and complete account of joint wiping that is published.

25 CENTS, POSTPAID.

DAVID WILLIAMS CO.,
232-238 William St., NEW YORK.

The Climax Gas Machine and Gas Mixer produces a steady, brilliant, highly satisfactory gas, free from smoke, which burns through plain non-regulating or Welsbach burners.

It is a modern, perfected apparatus, warranted satisfactory and guaranteed unsurpassed in any particular. For completeness, convenience and simplicity it has no equal. Sells to good trade who want the best and most desirable and will not submit to the objections of the old time machine, viz.: smoke and adjustable burners. Send for catalogue.

The Holiday Trade.

The general prosperity which the year just closing has brought to the people of this country is strikingly reflected in the great volume of business that has been done by merchants who cater to the holiday trade. The stores have been thronged by greater crowds than ever before, and it is a matter of general comment that the goods called for by the Christmas purchasers generally were of a considerably higher and more expensive class than heretofore. Manufacturers and retailers of holiday goods have been pushed to the utmost to meet the demand, and in many instances have found it impossible to satisfy the pressing requirements of their customers. This feature has been the only cause of complaint. Aside from the increased volume of business, prices in general have been satisfactory, and the margin of profit to the manufacturer and the merchant has probably been better than the average of past seasons. The beneficent spirit of Christmas has prevailed in full force among the eager crowd of liberal buyers who have thronged the streets and stores of the city in greater masses than ever before. The general prosperity is further demonstrated by the great volume and variety of the merchandise which has filled the warehouses and counters of the storekeepers. The finest productions of art, science and literature, as well as the more material necessities of life, have been offered in prodigal abundance to purchasers, and have been eagerly secured, even by those who ordinarily have had to content themselves with less costly wares. It has been the privilege of the many rather than of the few at this prosperous season to indulge in the luxury of buying and making gifts worth the having. In this reign of prosperity and satisfaction we trust all of our readers have had a full share.

Wireless Telegraphy Up to Date.

The close of the first year of the twentieth century has seen the beginnings of a remarkable development, if the statement of Signor Marconi that he has succeeded in telegraphing across the ocean without wires be substantiated. The experiments made a short time ago with the view of sending a message from the coast of Cornwall, England, to Newfoundland, while giving a promise of remarkable results when the system and apparatus used by Marconi are more fully perfected, were not so conclusive as to satisfy electricians and scientific men generally of the actual success of the system. Electricians believe in Marconi's ability, and have absolute faith in his integrity, but they are not yet convinced that the inventor may not have deceived himself in regard to the

fact of messages having reached him over the 2000 miles which intervene between the two continents. They call for something more definite than has up to the present been presented, and Marconi promises that the proofs shall be given to them in due course. The importance of Marconi's feat, if it shall be proved to an absolute certainty, cannot be overestimated. He has already successfully sent wireless messages with ease over a distance of more than 300 miles, and he claims that, with his improved apparatus, the principles of his discovery can be readily applied to far greater distances than that. The scientific world and the public at large will await with intense interest the outcome of the further experiments that are to be made in this field by the eminent discoverer.

The Car Shortage

The interruption of business caused by the shortage of cars continues as great as ever. A number of manufacturing establishments have been obliged to close down in the past week or two, owing to the impossibility of obtaining supplies of fuel. Many of the blast furnaces in the Pittsburgh district and in the Central West have been banked down for days at a time through the lack of coke, and iron manufacturers are also seriously hampered in their efforts to ship their product in response to orders. The car famine is about the only adverse feature of the present situation. The demand for all classes of goods, particularly in the iron trade, is of immense proportions and shows no signs of let up. Under the circumstances, it is peculiarly aggravating to both producers and consumers that transportation facilities should be so inadequate when business is so unusually brisk. Unfortunately, no early relief from this inconvenience is in sight, although the various railroad companies and car building concerns are doing their best to get out new rolling stock. The situation caused by the shortage of transportation facilities is working considerable hardship to a number of the manufacturers who have unfilled orders on their books, and also to the workmen who are placed in idleness owing to the enforced closing of the manufacturing plants at a time when they should be in full operation.

Guaranteeing Prices.

This is a season when in the ordinary course of things many goods are sold under a guarantee as to prices in one form or another. A reminder to the manufacturers and the jobbers as well of the manifold mischief of the practice is therefore timely. There is indeed little to be said in favor of the guarantee when the interests of the manufacturers and the trade as a whole are considered, and as it often operates, it falls to be advantageous even to the buyer for whose benefit it has been granted. The inequity of the practice and the disturbance which it causes to the trade are thus forcibly stated by a prominent manufacturer:

A guarantee is a most excellent thing for a buyer who wants to settle for the goods regardless of the seller's wishes. This would be particularly true if he were the only one who had a guarantee. But as a rule guarantees are a most pernicious thing—bad for both buyer and seller; they encourage unfair

dealings and unpleasant relations between the manufacturer and his customer. It is unbusinesslike on the part of the manufacturer, because he will not know what price he is going to get for his goods until payment day comes, and then some competitor makes the price. The market is demoralized, not simply to the manufacturer, but to the jobber as well. The large jobber has no advantage over the man who buys just enough to be recognized as a jobber by the manufacturer; in fact, the small jobber may be unprincipled, or, if fair, he may be very shrewd, and give the matter his particular personal attention, and under a guarantee get a price that the jobber buying several carloads could not get. Should guarantees become general, they might in time become equally general with the jobber selling the retailer, and as the jobber has from 10 to 50 or more accounts on his ledger than the manufacturer, it is easy to see who would be the sufferer.

Some progressive and broad minded jobbers have frankly acknowledged the evils of the guarantee system, and there is ground for hoping that it may under the prevalence of better principles and methods in commercial life be abandoned as unbusinesslike. A firm stand by representative jobbers in opposition to it would be a marked advance and would have much influence in helping to do away with the pernicious practice.

Should the principle of arbitration and conciliation embodied in the formation of the Industrial Department of the National Civic Federation be carried into successful effect, as all who are interested in the welfare of the country earnestly desire, the occupation of the walking delegate and the professional agitator will be gone. Under the new *régime*, which it is hoped to introduce, the settlement of labor troubles will require the negotiations of no middlemen. No place will be found for those troublesome functionaries, and probably none but themselves will be grieved over their disappearance from the industrial arena.

Decline of Individual Dwelling Houses in New York City.

Some interesting statistics concerning the decline in the number of individual dwelling houses in New York have been gathered by the local real estate paper, the *Record and Guide*. In these statistics the number of houses of this character projected each year is shown to have steadily decreased in the past ten years. It was at its highest in 1890, when plans were filed for 835 dwellings, and it reached its lowest point, so far as number is concerned, during the first ten months of 1901, in which plans for only 97 dwellings were recorded at the Building Department. The average cost of such houses, however, has increased very materially. The main cause for the decline in the building of dwellings no doubt has been the erection of so many large new apartment houses, which, in the improved accommodations they offer, compete effectually with private dwellings. A very large number of these apartment buildings have been erected in New York City during the past few years, especially on the West Side, a district that was for long monopolized by private dwellings. These new apartment houses are supplied with all the modern improvements and with many conveniences, and even luxuries, that are practically unattainable in a private house. Furthermore, the greatly enhanced value of land in the city has so materially increased the cost of buying lots for the erection of homes that the building of separate dwellings has been put practically beyond the reach of any but the more wealthy citizens. Residential New York, in fact, has become in recent years a city of apartment houses rather than homes. While the restricted area on which buildings can be erected and the rapid growth of the city's population have made this change inevitable, there are reasons for regretting the change, as tending, in a measure, to obliterate the gen-

uine home life which is fostered by the tenancy of separate dwellings in a city.

Advices from the City of Mexico state that plans have taken definite shape for the establishment there of a permanent exposition of the different manufactured articles which are imported into Mexico, as well as the products of the Republic. The Mexican Permanent Exposition Company, Limited, have just been incorporated with a capital stock of \$300,000, and have been granted a Government concession, by the terms of which the company guarantee to erect buildings for the display of goods, and to keep these in repair at their own expense. The cost of the buildings and the site is estimated at \$300,000. The exposition is to be completed and ready for opening within two years. The Exposition Company are empowered to make a charge for space to the exhibitors, and are required to publish catalogues in Spanish, English, French, German and Italian of all the goods displayed, the Government allowing the company to import such materials as may be needed for the construction of the buildings free of charge, while all imported articles for exhibition can be brought into the country under bond for one year. If not exported at the end of that time they will pay the regular duty.

Efforts are being made by the League for Social Service of New York City to establish a museum for the exhibition of devices and appliances for the prevention of accidents to workmen, similar to an institution of this character that has existed for some time in Amsterdam, Holland, under the name of the Museum of Security. The effect of the Amsterdam museum is said to have been to educate manufacturers and employers of labor in a practical manner as to the value and utility of adopting the various methods and appliances there exhibited, with a view to lessening danger to workmen by accident. The Dutch labor inspectors say that the museum is an excellent object lesson and that it facilitates their work in carrying into effect the necessary safeguards in manufacturing plants, as they can refer any manufacturer who does not see his way clear to providing the necessary precautions against accident, to appliances exhibited in the museum that will fit his case.

By the passage of the Industrial Arbitration bill through the Legislative Council of the colony, the Government of New South Wales has placed a law on its statute books the operation of which will be watched with great interest throughout the world. According to the terms of the law all disputes between employers and employed must be referred to a competent court with power to enforce its orders and awards. The law makes a strike or lockout before or pending such reference a misdemeanor, punishable by fine or imprisonment. The court which will pass upon these disputes will be presided over by a judge of the Supreme Court, who is given very extensive powers, including power to declare a standard wage and to direct that, other things being equal, an employer shall give preference to union over nonunion labor. There is no appeal from the decisions of this court.

It would seem that the limit to the height of the lofty business structures of down town New York has by no means yet been reached, if a report which was current this week is true. According to this report a promoter is trying to organize a realty company to build a 54-story office building on lower Broadway. It is said that plans for the building have already been drawn, and that from the street level to the top of the tower the height will be more than 700 feet. The estimated cost of the building is said to be about \$8,000,000.

The Mexican Central Railroad Company are equipping some of their locomotives with oil burners, and contemplate extending this fuel throughout their system. By the use of oil it is expected that the operating expense item of fuel, which was over \$3,000,000 (Mexican currency) in the last fiscal year, will be materially reduced.

THE PHILADELPHIA STOVE TRADE.

After a period of considerable activity the stove trade in Philadelphia has settled down to the usual holiday period of quietness. With almost all of the dealers and manufacturers the past season has been a most satisfactory one. The volume of general business transacted has been large, and with some it has been called a "banner" year. It has, however, had its disadvantages. Considerable disappointment and loss of sales have been occasioned by the inability to make deliveries on many lines of goods. The need of more molders, in some cases, has hampered the manufacturers of cast goods, while the great scarcity of sheets, due largely to the strike of the Amalgamated Association of Iron, Steel and Tin Workers in the Middle West during the summer months, as well as the increased general demand for that class of goods, has made it impossible for manufacturers using sheets in the construction of their goods to make deliveries in any reasonable sort of time.

Original orders placed during the late summer months were in some cases not flattering. Dealers were said to be rather prone to delay deliveries of goods from two weeks to a month, but since then new business has come along with a rush and, in numerous cases, far exceeding the manufacturers' expectations. We are advised that the various lines of goods have generally been taken quite uniformly, no special lines having particular prominence. Offerings of new goods have met with favor, and large sales of this class have been made.

The January trips of the various representatives of the stove houses are being looked forward to with a view of continued activity, and unless the signs fail there will be no disappointment from that source. The month just past has been reported by many manufacturers to have been the best December so far as business in their respective lines is concerned that they had for a number of years, and, all in all, the trade generally is well satisfied with the existing conditions.

SOFT COAL BURNING FOR DOMESTIC USE.

BY IN TOUCH.

The following editorial on the use of soft coal in domestic cooking and heating apparatus was presented recently in the New York *Herald*:

A Colossal Fortune is Awaiting Him.

The recent unprecedented series of fogs in London has revived interest in the movement for the abolition of the soft coal smoke which is such an important ingredient in the nuisance.

They are getting on. It was only in 1273 that this movement began. Stow chronicles the fact that in that year the use of sea coal in and near London was prohibited as being "prejudicial to human health." A special cable dispatch to the *Herald* this morning notes that at a meeting of great scientists just held to deal with the problem they adopted a resolution iterating the fact in almost precisely the same words—and adjourned.

The London County Council is now studying the matter, and some time in this century or the next will doubtless "report progress." An inventive Yankee ought to go over and patent a contrivance to burn soft coal for domestic use consuming its own smoke and saving the "heat," two-thirds of which now goes up the open chimneys.

Incidentally, we could use a few million stoves of that sort in America, to the delight of householders and the discomfiture of the anthracite trust. The man who produces the right device will reap a fortune that will make Mr. Carnegie's look like 30 cents.

The outside public is not aware of the large amount of time and money that has been expended in this field by inventors and theorists; neither do the trade outside of the soft coal regions know much about its history. While practical manufacturers have worked for years on the problem of constructing stoves for soft coal burning and have spent thousands of dollars, outsiders have also sunk lots of money in the same manner. But the solution of the problem has not yet been accepted, although some very excellent soft coal burning stoves are on the market. How big a field awaits the successful construction is shown by the *Herald* editorial.

It is strictly true that the field for such stoves is im-

mense, as it extends all over the world wherever soft coal is used. The stove manufacturer who has worked this field and watched it carefully has accumulated a stock of information and experience that renders his judgment valuable, and enables him to see the merits of the perfect stove for soft coal combustion. He has failed so far to recognize it in any of the constructions brought to his notice. On the other hand, outsiders have taken the subject up, and after simply seeing a stove in operation under the manipulation of an inventor or promoter have put down lots of money on the representation that a fortune can be reaped from the enormous demand that is represented to them as awaiting the production of such stoves. So far as the promoter's side of the picture is concerned, the *Herald's* editorial confirms the claim as to the number of stoves that could be sold. But as none of the parties referred to have ever seen or known anything about stoves and the intricacies of their manufacture, they naturally presume that all that is necessary is to get up a stove on that line and the profits will roll in.

The following history of one of those operations may be of interest and will not detract anything from the merits of such inventions. It is merely an illustration of what has been experienced in this field: Several soft coal stoves were exhibited privately in New York some years ago, one of which was in the hands of promoters. When another inventor came to town to exploit his stove he also fell in with one of the promoters. This promoter succeeded in getting some rich capitalists interested in the matter, as the principle embodied in the stove was also applicable to steam boilers, &c. So far as getting up the company and obtaining ample means were concerned it was successful. When the business began an expert was engaged at a big salary to get up the stove and put it on the market. But the stove "failed to materialize."

Meanwhile the promoter had mastered the subject of combustion and how to make and sell stoves so well that he proposed to show the stove men that they were "not alive, not in it," as he expressed it. In short, he knew it all. It is to be said to his credit that he had studied the theory and practice of combustion thoroughly, and could give points to the average stove man in talking about it. But when he undertook to make and sell his stove, and incidentally show the stove makers how to do business, it must be said he was a failure.

It might be possible to learn some kinds of business in a day or two, but any one who can master the stove business in so short a time as this promoter claimed to have done it in would be, indeed, a wonder and could command a big salary, for he would revolutionize the business. Now this is what he did do. He put draftsmen to work, got all his drawings out, set the pattern makers to work, and the stove, although time enough has elapsed, is not yet in possession of the public to that degree that they are tumbling over each other to get it. It is estimated that \$50,000 cash was spent on this stove. Of course, this includes the expense account. So far as the principle was applied to power boiler fire boxes it is said to be a success; but nothing is said about profits.

According to the *Herald* editorial, the promoter was on the right track and had a big field for his work, for it makes a bigger claim for it than he did. Is it not a fact that stove makers do not know all the possibilities of the business, judging from the way they sit down on the ideas of others?

There is no question about the field for stoves for burning soft coal without smoke, and not only for those, but for furnaces for steaming purposes. But outsiders who think they can succeed in the stove business and get the fortunes out of it that there may be in it will have to pursue other methods than those recorded.

So far as cooking and heating stoves are concerned, do away with the smoke and soot, or reduce it to a minimum, and they will always be in great demand.

THE WARWICK FURNACE MFG. COMPANY of Massillon, Ohio, have been incorporated with a capital of \$20,000 by W. H. Geiss, D. S. Sauers, H. W. Loeffler, J. N. Merwin and S. T. McMeeken.

VENTILATION IN CONNECTION WITH FURNACE WORK.

BY ANTI COMPRESSION.

The extract from the letter of a correspondent, presented recently in *The Metal Worker*, calling attention to the fact that ventilation is needed in connection with furnace work, heartily meets my approval, and the sooner all furnace men understand this the less complaint they will have in regard to their work. It is a fixed law in nature that two things cannot occupy the same place at the same time. That is to say, when the fire pot of a furnace is heaped full, no more coal can be put on until the ashes are removed from the bottom. From the fact that the coal and the ashes can be seen as substance, and handled in a positive manner, there is no difficulty in getting the most skeptical to admit the correctness of this statement. When, however, difficulty is experienced in heating some room connected with a hot air furnace, the application of this law to such invisible matter as air cannot be discerned by many who do excellent furnace work.

Whenever a furnace is properly supplied with air and has no more hot air pipes leading from it than it can reasonably fill, air should flow in equal volume from all the pipes. When air fails to flow freely from some one pipe, or stops, the investigation for the cause of the stoppage should be conducted along these lines: First, find if the windows fit tight, if weather strips or double sashes are provided, and if there is a ventilating flue, a chimney, or a grate in the room, and if the difficulty is most pronounced when the door of the room is closed. If the windows fit tight and there is no chimney hole, or open grate in the room, and the difficulty is experienced when the door is closed, the solution of the trouble is a simple matter to an experienced man.

VENTILATION.

This is simply the result of the room being full of air and there being no outlet by which the air that is in it can escape, so that it is impossible for warm air to enter. The opening of a door can always be relied upon to start a circulation. Sometimes the desire for privacy will cause the door to be closed. Such being the condition, the furnace man must arrange for the escape of the air that is in the room. In many residences that are fitted with double sashes, the whole heating system operates erratically if there is no provision for the air to escape, but such a condition can be avoided if an open grate with a flue of sufficient capacity is provided in the main hall when the building is erected. The grate, whether there is a fire in it or not, if its flue is beside the furnace flue, will be warmed sufficiently to induce an exhaust current and continually draw from the building a sufficient quantity of air to facilitate the inflow of warm air from every register in the building.

For general use this is essential. Sometimes, however, the furnace man is confronted with difficulty in a building in which no grate and flue have been provided. If there is an unused flue in the chimney, benefit will be derived by running a pipe to it from a register in the floor of the hall. In the absence of such a flue, however, when the furnace chimney has a sufficiently strong draft, it may sometimes be utilized for the same purpose, dampers being provided to shut off the ventilation when it is necessary that the furnace fire shall be subject to the full draft of the chimney, to make it burn up briskly. These suggestions are all to the end of ventilation, which means to remove some air from the building and make room for fresh air. This is one of the features of the furnace system that has made it popular in all the vicissitudes through which it has passed, notwithstanding the many poor examples of work that are in existence.

CIRCULATION.

When ventilation pure and simple cannot be secured, circulation can be resorted to. In residences where there is a large body of air in proportion to the small number of people, there can be but little objection to circulation of the air in the building to facilitate the heating, provided arrangements are also made to take air from out

of doors at some time during the day. If the air is to be circulated there should be a register in the floor of the main hall having openings of the same area as the combined hot air outlets. There should be no difficulty whatever in heating a building having such a system, if the doors to the various rooms, or the transoms, are left open to facilitate the circulation.

To return to the consideration of the air bound room with its door closed, relief can be always secured by running a pipe from the floor of the room to the bottom of the furnace, and in case the regular outside air supply interferes with it, it is a simple matter to turn the mouth of this pipe upward on the inside of the furnace. If this pipe is made the same size as the hot air pipe to the room, greater satisfaction will be derived. The use of a return air duct can also frequently be made with advantage in rooms which have a large glass exposure, particularly when it is a bay window. The warm air in the room will naturally cool and fall along the glass in the bay window, and if a register is placed to gather this cooled air and carry it back to the furnace to be heated, it will go a long way toward aiding the heating of the room and avoiding a difference in the temperature in different parts of the room.

COMPRESSING AIR.

Experience has demonstrated that it takes considerable power to compress air to any considerable extent, but there is no such power exerted in the movement of air in furnace heating systems. It is remarkable that furnace systems are so generally satisfactory, when it is considered that the movement of the air depends entirely upon the difference in the weight of the air before and after it is heated. The upward movement of the hot air is due to the fact that the heavier, cooler air supplied to the furnace is continually sinking down and pressing the heated air upward. If furnace men would consider this fact more carefully they would use greater care in providing round elbows and taking off sharp corners of flues which retard the flow of air and add to the friction of its passage through the pipe and flues.

SOME HARD KNOTS IN FURNACE PRACTICE.

BY OLD ROSINHEAD.

With the express purpose of getting up a discussion through the columns of your valuable paper on the various difficulties encountered at times with hot air furnace heating and their remedies, I present the following remarks. Will some of the many men who are interested in furnace heating from various standpoints take part in the discussion and either controvert or verify, and also supply information on other knots that we have not encountered?

To start with, the furnaceman must ascend to the point of understanding that there are several fixed and unalterable natural laws governing the case, and, furthermore, to the realization that certain forces did exist, and were harnessed and in practical use in other branches of mechanics, probably long before hot air furnaces came into existence. Therefore we are inclined to believe that when a furnaceman meets with a difficulty in his work it will be necessary to drop all ideas about furnaces and reach out into the realms of other pursuits, where like causes produce like results. If he studies the subject deeply and long, he, no doubt, will be able to discover the remedies and be able to apply them successfully and without calling in the aid of other furnacemen, or looking for other furnace jobs to pattern after.

The cold air surrounding the earth is heated by refraction of the sun's rays on the surface of the earth, and in no wise do these rays have any great effect except by refraction. The tendency of this heated air is to rise, but this action is not so rapid or so intense but that spaces are found where shafts of cold air can penetrate through the body of hot air, and thus also be heated in their turn. The furnaceman who entertains doubts about the workings of a cold air supply, or a cold air return, need only revert to the fact that cold air is drawn down into the bowels of the earth 200 or 300 feet through a shaft by suspending, in a connecting shaft, an iron basket with a fire in it. By so doing miles of mine galleries have

been ventilated—a great big and long cold air return, surely. And this kind of a job was done long before furnaces came into vogue, if I am not mistaken.

Hot air, like lightning, flows where it meets with least resistance. When resistance is met with in its upward course it swerves to one side and flows till it is beyond the influence of such resistance, then it ascends again. Then what resistance does hot air meet with in a horizontal round pipe? Presumably, only its own friction in passing through the pipe, irrespective of the direction in which the pipe is run. The resistance is encountered at the register box where it enters the cold room, and nowhere else. Some registers are so located in some of the rooms of a big furnace job that the normal downward atmospheric pressure at that point is greater than the artificial upward pressure furnished from the furnace; hence no hot air can force its way up into the room. It is a warfare of one of the forces of nature against another force, and the weaker fails as a matter of course. Locate the register at a point in the room where these two forces cannot clash.

In some of these cases the hot air pipe is converted into a cold air return, and this is brought about by certain conditions existing at the hood of the furnace. Lots of old furnacemen will laugh when asked if they understand the principle of a jet pump or injector, and wherein the same principle is applied detrimentally to a hot air furnace. Yet the same principles do exert a controlling influence over parts of a hot air furnace. The rapid rush of a volume of hot air to the inlet to a very large pipe will, in some instances, create a vacuum at the inlet to a smaller adjoining pipe, and this vacuum moves up into the pipe, with the result that the downward pressure of the cold air in the room where the register is not in the right place will meet with no resistance, and the pipe will exert all its influence to pour into and mingle with the hot a body of cold air, and thereby deaden the heating effect in the other parts of the house.

Monarch Malleable Iron and Steel Ranges.

A very neatly printed catalogue of 24 pages, bound in paper covers, with side title in red and green, has been issued from the press by the Malleable Iron Range Company of Beaver Dam, Wis., recently located at St. Louis, Mo. Among the early pages are found directions with a description of the construction of the Monarch range. Illustrations are also presented showing general views of some of the varieties manufactured, as well as of special features to which attention is drawn in the descriptive text. The general make up of the catalogue indicates a thorough knowledge of the requirements of the trade, and the matter is presented in a way which cannot fail to attract the attention of the consumer as well as the dealer handling the various lines. In addition to the Monarch, reference is made to the Mound City range, and also to Terrell's tubular coal heater, which is represented with a part of the outer casing broken away, clearly indicating the internal construction. Terrell's hot blast heater and Terrell's tubular wood heater are also illustrated and described. The closing page in the catalogue is devoted to a few comments on drafts, flues and the operation of the ranges, as well as directions for setting up steel ranges.

ODD PLATES.

With the compliments of the Presbrey Stove Lining Company, Taunton, Mass., we have received one of the pretty wall calendars that they are distributing this season. The main feature of the card is a fine half-tone reproduction of Boughton's picture of the "Return of the Mayflower." The card is of blue, decorated with gold, the calendar sheets being attached to the lower part.

We have received, with the compliments of Fred W. Gardner, Western manager of the Michigan Stove Company, Chicago, a box containing a supply of lead pencils and a very neat sterling silver holder, which enables the pencils to be carried in the pocket without exposing the point. The holder is tipped with rubber, thus combining in the outfit everything needed by the user of

the pencil. The customers of the Michigan Stove Company who receive this holiday gift will find the pencils of excellent quality, and we have no doubt that they will be largely used in writing orders for Garland Stoves and Ranges.

THE MICHIGAN STOVE COMPANY have favored the trade with two artistic circulars lithographed in colors. One of these circulars, in addition to showing scenes from child life, is used for the purpose of illustrating and describing the Art Garland Junior, a base burner, intended for anthracite coal or crushed coke, made in three sizes. It is not only constructed to secure the best results as a heater, but it is also artistically designed and superbly decorated. The other circular treats of the Surprise-Garland steel cook, which is adapted to the use of either coal or wood. This stove is offered as one of the most durable steel cooking stoves ever brought out. It is provided with an aerated oven, and is finished with an attractively designed cast base and with the doors trimmed with finely carved cast work.

JOHN W. HOLMES, for the past 20 years chief foundry foreman of the Michigan Stove Company of Detroit, has resigned his position, to take effect in the near future.

THE IRELAND & MATTHEWS COMPANY, manufacturers of Stove Trimmings and Brass Goods, Detroit, Mich., are arranging for the construction of a fourth story over their present factory building, which is about 150 x 160 feet in size. The addition of this story will give the company a total of 24,000 feet of floor space. They recently occupied a two-story brick building erected to be used as a brass foundry. A new power plant will shortly be added, in which will be placed a 300 horse-power cross compound engine and a large Wickes vertical tubular boiler. They will further install a 300 horse-power electric generator in the power plant.

THE KEYSTONE STOVE FOUNDRY of Spring City, Pa., were granted a charter at Harrisburg on December 18 with a capital of \$60,000. This incorporation, we understand, is the outgrowth of the former Spring Valley Stove Company, and the new concern will commence active operations shortly after January 1 with a force of about 60 hands. The officers of the concern are: President, E. B. Colby of New York city; general manager, J. Edgar Diemer of Spring City, Pa., and treasurer, Irwin Cairns of Park place, N. J.

THE AMERICAN STOVE COMPANY is the name of a concern who filed papers of incorporation in the State of New Jersey on December 19, the capital stock being placed at \$125,000. The incorporators are: Clifford W. Perkins, A. S. Meeker and K. K. McLaren. It is intimated, although the rumor lacks confirmation, that the company are to form the nucleus of a combination of Stove manufacturers, and that the capital is to be increased to several million dollars.

THE ABRAM COX STOVE COMPANY of Philadelphia, Pa., were incorporated at Harrisburg on Thursday, December 19, the capital stock being placed at \$150,000. The charter of the company had expired, hence the taking out of a new one. The incorporation, however, in no way affects the character of the company.

THE Quick Meal Steel Ranges, Oil, Gas and Gasoline Stoves, with the familiar trade-mark of the Ringen Stove Company, St. Louis, Mo., appear on the top of a calendar for 1902, with which we have been favored by the manufacturers. The calendar is arranged in weekly sheets with blank spaces against each for notes. It is mounted on a metal back, and arranged either for hanging on a wall, or standing upon a table, having an easel attachment which can be used for the latter purpose. The calendar will no doubt be found useful, and be greatly appreciated by those who receive it.

THE SOMERSET STOVE FOUNDRY COMPANY of Somerset, Mass., manufacturers of the Glendale and Somerset Stoves and Ranges, have favored us with a copy of a pretty wall calendar for 1902, which they are distributing to their friends in the trade. The leading feature of the calendar is a very artistic reproduction of a painting of poppies and wild flowers, the calendar sheets being attached to the bottom of the card. On account of the decorative feature the calendar is sure to be given a place of honor in the Stove dealer's office.

THE business of Moore Brothers, at Wichita, Kan., has increased to such an extent that they have found it necessary to erect an addition to their foundry and warehouses, which will double their capacity. It is expected that the warehouse will be 50 x 150 feet in size, and two stories in height. The warehouse will be used for the storage of Stoves and also for the stock of heavy irons, such as Eye Beams and other structural material, which they will carry in the future. The concern also contemplates the erection of a new furnace, which will enable them to melt about 10 tons of iron a day, instead of 4 or 5, as is now the case.

AN ornamental panel of irregular outline and printed in colors is the basis of a calendar for the new year, which is being distributed with the compliments of the Danville Stove & Mfg. Company of Danville, Pa. The picture with which the panel is embellished represents an interior with two little girls sitting at a window, while one holds in her lap an open book. The text consists of the addresses of the branches of the company in Philadelphia, New York, Pittsburgh and Chicago. Attached to the lower part of the panel, which is provided with a metal eye for hanging up, are 12 leaflets with the days of the week and month appearing in white letters upon a solid black ground. Included in the astronomical information are the different phases of the moon. A thirteenth leaflet is devoted to a calendar for the year. In this case the days of the week and month appear in black letters upon a white ground.

SHORTLY before midnight on December 18 fire was discovered in a six-story building on West Fayette street, Baltimore, Md., occupied by several business firms. Among the sufferers were Isaac A. Sheppard & Co., the well-known Stove manufacturers.

Vanderman's Hood Coupling.

Where waste and vent pipes pass through cement and marble floors and through roofs, the necessity for a tight joint which will also allow free expansion of the pipe has been one of the difficulties which the plumber

Fig. 1.—Floor Connection.

Fig. 2.—Roof Connection.

Vanderman's Hood Coupling.

has had to deal with. The Vanderman Plumbing & Heating Company of Willimantic, Conn., are placing on the market a hood coupling, which is designed to be used in connection with a thimble imbedded in the cement or marble floor, as shown in Fig. 1. A sectional view is presented in Fig. 2, showing its use where pipes must pass through the roof. This coupling is designed for use in connection with wrought iron pipe of all sizes, from $\frac{3}{4}$ inch to 12 inch. The coupling is threaded both top and bottom. At the bottom it is enlarged to slip over the pipe as a sleeve and cover the metal thimble which projects up into it. It is pointed out that by this means a perfectly watertight connection can be made wherever the coupling is used.

A Christmas Carol?

The poet of the Canfield Supply Company, Kingston, N. Y., has evidently been inspired again, for in the company's large show window, which is decorated with handsome tea and coffee pots, stands a big card with the following verses printed on it:

Santa Claus with Christmas joys
Brings other things than simple toys;
Gifts to fill the heart with cheer
And keep you happy all the year.

Could you peep into the sack,
Hanging so full upon his back,
You'd see among the bundles queer
Many that came right out of here.

Tea pots nickeled up so fine
And coffee pots that brightly shine.
Kettles, too, perchance you'd see,
To hang on some one's Christmas tree.

Get in line, step right inside;
Fill some one's heart with honest pride.
Christmas morn when you awake
You'll see that you made no mistake.

Goulds' Sentinel, Jr., Double Acting Spray Pump.

The Goulds Mfg. Company, Seneca Falls, N. Y., are offering the double acting spray pump illustrated here—

Goulds' Sentinel, Jr., Double Acting Spray Pump.

with. It is designed especially for the requirements of orchardists and orange growers desiring quick work at high pressure. Notwithstanding the large capacity of the pump, it is remarked, one man can operate it constantly against over 100 pounds pressure without undue effort. It is explained that the pump is often used with six nozzles on the end of one extension pipe; also with several leads of hose. It is pointed out that the piston is easily and quickly repacked; that all valves are easily accessible; that the piston, piston rod, valves, valve seats and cylinder lining are brass; that the piston rod is outside guided, so that it runs perfectly straight, and that the air chamber is 5 x 30 inches in size. The pump when ordered without hose has 1-inch suction and two $\frac{1}{2}$ -inch discharge brass hose couplings, also brass strainer. Brass Y's for fitting two leads of discharge hose on a side are furnished when ordered. Hose can be furnished in any length and any number of leads, double nozzles, extensions, &c.

HAVANA HARBOR.

A window display that attracted much attention and kept a crowd of interested spectators in front of the Hardware store of C. Magnussen, Lyons, Iowa, both during the daytime and evening, is shown in Fig. 1. The

water and the grooved pulley connected with a small steam engine of 1-40 horse-power, that caused the boats to revolve slowly. The side walls of the window were used to display Guns and Fishing Tackle. Fig. 3 shows the write-up given the display in the local paper. These notices can generally be secured if the dealer advertises

Fig. 1.—Havana Harbor.

background was formed of a painted picture of Morro Castle, in front of which was placed a model of the ill fated battle ship "Maine." In the bottom of the window was set a pan 6 feet square and 5 inches deep. In

and makes a request for them when he has something of particular interest in his window.

The Tennessee Hand Grinding Mill.

A. H. Patch, Clarksville, Tenn., is offering the hand grinding mill shown herewith. All bearings are chilled and the crank is of malleable iron. The grinding plates are made, it is remarked, of the hardest and strongest

Fig. 2.—Mechanism by Which Ships are Moved.

the center of this pan was soldered a 1/2-inch pipe, a hole being left in the bottom of the pan. Through this pipe was run a small shaft, to which were fastened wire

Fig. 1.—The Tennessee Hand Grinding Mill, Front View.

metals. The mill is designed for farm or family use, and is readily taken apart for cleaning or oiling, without the use of tools. New grinding plates can be inserted at

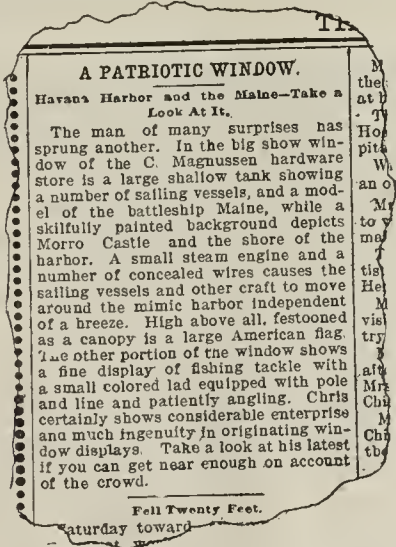

Fig. 3.—Clipping from Local Paper.

arms, the sail boats being attached as shown in Fig. 2. To the lower end of the vertical shaft was fastened a beveled gear, taken from an egg beater, which worked in another beveled gear on a horizontal shaft. On this shaft was a grooved pulley. The pan was filled with

Fig. 2.—The Tennessee Hand Grinding Mill, Rear View.

a small expense, it is remarked, whenever the original ones are worn out. The mill is adjustable for fine or coarse grinding of wheat, corn, rye or other dry grain. The mill weighs 12 pounds complete.

SUGGESTIONS FOR INVENTORY.

The following suggestions, which apply to taking account of stock, illustrate the methods adopted by an enterprising hardware house. The suggestions, in typewritten form, were distributed to the employees for their guidance in taking last year's inventory:

1. Sheets which we will use are the ordinary blanks which Mr. ——— uses for writing up orders. It is entirely proper to write on both sides, and better, from the fact that the bulk of books when bound finally will be smaller. Please be careful that the two holes on the left hand side of the pages are not torn, as the sheets will be bound using these holes.

2. We want you to think as you read and see where these suggestions in regard to inventory are good, and as you work, in either stock or writing down, have matters clear whether they are touched upon in these suggestions or not.

3. Do not write upon the two top lines of any sheet.

4. Do not write upon the two bottom lines of any sheet.

5. At the head of each sheet indicate the part of the store covered by it.

6. Be sure that the space of one line is left between items of different kinds. This applies to different items of the same kind of goods. For instance, there should be a line left between Flat Head Bright Screws and Flat Head Brass Screws or other goods. Also, for instance, No. 7 Hand Saws and D 8 Hand Saws would take a different discount and a line should be left between them.

7. We wish you to be careful that all goods of a certain kind are written under each other. For instance, if No. 11 Chest Handles were in one row of shelves and No. 12 in another the goods should be rearranged so that all Chest Handles will be together, and the inventory of Chest Handles will all be in immediate sequence. This is very important for the proper arrangement of inventory and we will ask you to be careful about it.

8. The only exception to the above is in Builders' Hardware. Mr. ——— has an especial arrangement for this line of goods and inventory should be taken with this arrangement in mind. This, however, Mr. ——— will attend to.

9. Each evening we wish those working on inventory to stop at 5 o'clock and have all of the sheets which they have taken during the day priced, extended and added. The addition which you make must come immediately under the columns in which you make the extension. We do not wish you to use the last three columns which are on the sheets for figures.

10. We will furnish each of you a separate want book, which you will find divided as follows:

a. Wants.—Under this head make a notation of all short items for which orders should be placed. At the end of each evening transfer from this want book such items only as should be ordered immediately, in such case marking out or checking off the item added on the general want book.

b. Goods Which Should Have Sample Boards Made for Them or Some Better Display Devised.—Under this division simply make a memorandum of goods and after inventory is completed, at our convenience, we will properly provide some display.

c. Goods Which Are Bad Stock, or Odds and Ends.—As in above case, simply make a notation of this, and we can afterward go over them.

d. Goods Which Should be Marked, or Additional Lists Made, or Prices Corrected.—Under this head you will simply make a notation of where you think prices should be corrected, or a notation where goods are not marked and should be marked, or where other lists besides the one in the price book at the front of the store should be put near the stock. For instance, the writer is working now on a list of Hames, which we have not had and which should have been made. This is the kind of thing that you want to note under this column.

The suggestions that are gotten up in this book we do not wish brought up until after the inventory is complete, unless there is some very important matter which should claim our immediate attention. It is simply an arrangement for afterward getting our stock and facilities for prompt and accurate sales in better condition.

11. We wish you to leave all stock in absolutely clean condition, taking out the goods from where they are stored and sprinkling and sweeping underneath. Let us have a nice clean store, as far as the corners and out of the way places are concerned, after our inventory is completed.

12. All shelves and bins should have all of the goods taken out and be brushed out. It is a very good plan to have with you a box of damp sawdust for sprinkling in shelf. Then dust the same out or wipe it with a damp cloth. This will diminish materially the dust floating around the store and will add a good deal to your comfort in cleaning.

13. Where two or more boxes have been opened one of the boxes should be filled. For instance, if one of the boxes of No. 1036 Padiocks has seven in it and another one eight, make one of the boxes a full dozen, leaving one box with the remaining three locks in it. Do not carry this matter too far and throw away boxes which might be used. It is not a bad plan to have an empty box, with the proper number on it, convenient for use where orders call for less than a package.

14. We wish you would be careful in going over the stock to see where you think it advisable to oil certain goods. For instance, see that Cross Cut Saws, Circular Saws and other things which you know will be liable to suffer from rust receive a slight coating of oil.

15. There will be a different man each day whom we do not expect to take any part in the inventory work unless it be the matter of some verbal information to some one. We will arrange this as follows:

a. From Wednesday, December 26 to Saturday, January 5, Mr. ———.

b. From Monday, January 7, to Saturday, January 12, Mr. ———.

c. From Monday, January 14, to Saturday, January 19, Mr. ———.

d. From Monday, January 21, to Saturday, January 26, Mr. ———.

16. On the morning of December 31 we wish the following stocks taken, regardless of your attention to other matters of inventory—that is, we want you to arrange among yourselves to take these items, leaving off your work in other items:

a. Nails, both kegs down stairs and broken lots in bins.

b. Horseshoes, both full kegs down stairs and broken lots in bins up stairs.

c. Bar Iron.

d. Loaded Shells, Cartridges, both full cases and broken lines in shelves.

e. Shot, both in case in front and bags in rear.

f. Powder, both in canteens in front and Powder in magazine at side of store.

Mr. ——— will on this date take the stock of Machine Needles, and in doing so will please estimate the ones in bins.

17. The following is as important as anything, and we wish each of you to get it into your records very distinctly.

a. Up to night of December 31 enter all goods which you sell which have been taken.

b. On the morning of January 1 and after enter all goods which you sell which have not been taken.

After the stock of any items is taken write a tag so stating and attach to the goods.

We wish each man writing up sheets to keep a consecutive number on all sheets written. For instance, Mr. A. would head his sheets "A" 1, 2, 3, 4, &c.; Mr. B. would head his sheets "B" 1, 2, 3, 4, &c.

At the end of the book of record of sales we will indicate quite a number of pages "List of goods which have been taken." Under this head, at the end of each night indicate the goods which have been taken. For instance, if Mr. ——— had the day before or the night before taken an inventory for Hames, simply write Hames down in this list. When it is necessary to make exception to such list they should properly note and then afterward erase. For instance, if Mr. ——— has taken all of the Hames except those in some particular location or some particular kind, he would indicate Hames except ———. When this inventory was complete he would simply erase the exception which he had made.

HARDWARE STORE WINDOW DISPLAY.

BY JAMES COOK SARCHET.

Window displays in most hardware stores in the smaller towns and cities are not changed often enough, and the goods shown frequently get soiled with fly specks and dust. The mistake in arranging show windows is in not placing the goods so as to attract attention. Goods displayed should be in season and up to date, and arranged so as to call to mind the needs of the hour, thus helping to increase sales. These will more than pay for the time it will take to fix up the windows. People in passing will see, and often purchase at once, what they will not need for weeks to come if the article is called to mind by a nice display.

HELPS TO ATTRACTIVE DISPLAYS.

Good shelving and fixtures help to show small goods. Swinging glass shelves make a good display rack, and do not cast as much shadow as wooden shelves. Mechanical appliances, such as water and electric motors, may at times be advantageously used for running mechanical toys, bicycles or some other form of moving display.

The light in the windows should be the best to be had. Electric lights make the best effects.

Backgrounds for windows should be bright and clean, and changed as often as the window is trimmed. A very good background is made by taking a frame work of wood built to fit the back of the window. Cover this with colored muslin or fancy colored paper on both sides, each side being of a different color, one side perhaps blue and the other red. These can be turned around very easily, and a change thus made in the color of the background.

VARIETY IN DISPLAY.

A variety in display is best. The more goods displayed the better, as a large show of goods will call attention to the large stock kept by the firm. Goods out of season should never be displayed. Goods in season or about to be should have the first place in all display windows. The window should be changed often and not left to become an eyesore to the public. It should be taken careful care of and dusted every morning. All bright goods should be rubbed to keep them from getting rusty.

MARKING PRICES.

Prices should not be put on all goods, as the competitor will be about the first one to learn them, and he will go one better. If it is necessary to mark prices on goods have them so low that there will be no danger from the other fellow.

Keep the window so that the public will talk about it. Always have something that is new and up to date to show and it cannot fail but win trade.

Stove and Hardware Dealers.

HIBBARD, SPENCER, BARTLETT & Co., Chicago, have decided to increase their capital stock from \$500,000, its present amount, to \$1,000,000. The increase is to meet the expense of extensions and improvements which they are to make in building new warehouses, to which reference has recently been made in these columns.

THE ELLIOTT MFG. COMPANY, Warren, Ill., are distributing an illustrated catalogue of the Elliott one-piece bottom Anti-Rusting Tinware—Pails, Dippers, Tea Kettles, Wash Boilers, Tea Pots, Coffee Pots and Boilers, Measures, Sprinklers, Wash Basins, Milk Pans, Sauce Pans, Preserving Kettles, Oil Cans, &c.

THE HOOD MFG. COMPANY, Carthage, Mo., manufacturers of Self Measuring Faucets, have bought a new building on Main street, into which they will move their manufacturing department. New machinery will be installed and the capacity considerably increased.

AUGUSTUS J. CORDIER, vice-president and general manager of the Lalanc & Grosjean Mfg. Company, New York, returned home in time for Christmas from a business trip to Chicago and St. Louis.

THE BOSS WASHING MACHINE COMPANY, Cincinnati, Ohio, who claim to be the manufacturers of the leading and best Clothes Washers, are sending out a calendar which will doubtless be popular with all who receive it. It is handsomely printed in colors, and the main feature of the card, which is 14 x 20 inches in size, is two representatives of Young America. The young man, in an officer's uniform, is holding an American flag, while his partner, a young girl in a pink dress, has a drum, and is said to be "drumming for the Boss Washing Machines."

H. MERKEL, 509-511 Elm street, St. Louis, Mo., manufacturer of the Simplicity Gasoline Lamps and Appliances, has issued circulars and price-lists of his well known line of goods. The assortment of styles covers a wider range than heretofore. We are informed that the demand for these goods is on the increase, and that orders have been filled to points in Japan, China, Philippine Islands, Cuba, Europe, South America, Central America and Canada. Mr. Merkel has entered largely into the manufacture of Mantles for lights, and is prepared to fill all requirements for this specialty.

THE Broiler patents owned by E. A. Leland, Great Barrington, Mass., have lately been purchased by Frank H. Wright and others, the intention being to arrange as soon as practicable for the manufacture of the Broiler Dies for stamping are now in course of preparation and will be about all the new equipment needed. The Broilers will be made of Sheet Iron.

THE WISCONSIN REFRIGERATOR COMPANY, Eau Claire, Wis., are sending out a new catalogue of the Wisconsin Peerless and Badger Refrigerators. These Refrigerators are made with a cleanable flue wall. This consists of a square hollow device attached to the center and inner side of the wall, forming a flue within a flue, thus aiding in the rapidity of the circulation. These side flues can be removed to be cleansed as desired. Specially designed fittings are used, such as a special form of ice rack and an efficient drain pipe and drip cup. The Peerless line occupies 52 pages of the catalogue, and is shown in a full variety of styles covering all constructions, including Sideboards for domestic use and large sizes for grocers and butchers. The last ten pages of the catalogue illustrate the Badger line, which is a well finished style of Refrigerators offered at a somewhat lower price.

A. M. BANNARD has sold his Hardware, Stove, Farm Machinery, Wagon, Buggy and furniture business, at Brownsville, Ore., to J. W. Ross, who will continue at the old stand. Mr. Bannard has acquired the furniture business of M. Wilbur, Grant's Pass., Ore., and expects later to enlarge it and add the sale of Stoves and General House Furnishings.

THE HENRY & WRIGHT MFG. COMPANY, composed of R. G. Henry, formerly superintendent, and D. M. Wright, formerly secretary and treasurer, of the American Specialty Mfg. Company, have succeeded the latter concern, and will continue business at 132 Sheldon street, Hartford, Conn., manufacturing Sheet Metal Blanks and Dies and Tools for same, light machinery and novelties under contract. They already manufacture a line of Hardware Specialties, including the Columbia and Twentieth Century Tack Pullers, and are preparing to bring out a line of Pruning Shears consisting of about 12 different styles.

HIBBARD, SPENCER, BARTLETT & Co., who are now erecting a large warehouse on the north side of the Chicago River, at Chicago, have in view even more extensive improvements. They have purchased the entire block extending along South Water street from Wabash avenue to State street, and lying along the Chicago River in the rear, on which they propose to erect a large store building which will eventually take the place of their present building at Lake street and Wabash avenue. The new property is located about one block northwest of their present store building. The block which has been purchased is now occupied by a number of business structures which are under lease until May 1, so that the beginning of the new building will necessarily be deferred until after that date. The location which has been chosen is advantageous in many respects, the navigation facilities being considered extremely desirable.

A CHALLENGE OF SCIENTIFIC AXIOMS.

BY J. C. BAYLES, M.E., PH.D.

A few days ago I fell in with a little book which gave me more entertainment in an hour than I usually manage to extract from reading in a month. It is not a humorous book, at least the author did not intend that it should be so regarded. He is in deadly earnest throughout, and with the implacable zeal of the iconoclast he attacks certain "Errors in Science Teaching." This, by the way, is the title of the little book in question, and the author is Prof. C. Stuart Gager of the State Normal College, Albany, N. Y.

Professor Gager's quarrel is not with the facts which are reasonably well established from observed phenomena, but with certain slipshod forms of expression embodied in most technical literature and all technical teaching, and which, failing to state the truth accurately, are supposed to be conducive to disjointed and inconclusive thinking. The first of the fallacies which the author attacks is that concealed in the familiar proposition,

HOT AIR TENDS TO RISE.

Professor Gager shows very clearly that it has no such tendency. This will make a good many readers of *The Metal Worker* "sit up" and rub their eyes. The trouble with this form of words, which is one of the heritages of the present from the past, is not with the phenomenon that hot air does rise when free to move, but that it has a "tendency" to do so. To speak by the card, it has no such tendency, any more than has a hot flat iron or a hot tamale. Hot air, as well as cold, is constantly acted on by gravity, and gravity imparts to it a tendency to move toward the center of the earth. Heating air does not correct this tendency or create a tendency to set gravity at defiance. What happens to cause air to circulate by the rising of that which is relatively warm and the falling of that which is relatively cold is described by Professor Gager as follows:

Suppose that the air of a room is at a given temperature. It is, then, other things being equal, of equal density throughout; but if a given cubic foot is heated it expands and occupies more than a cubic foot of space. Its weight remains the same, but the weight of the air it displaces after it is heated is greater than that of the air it displaced before it was heated; hence the buoyant force is greater than the weight of the heated air, which, in consequence, rises.

If one was disposed to be hypercritical he might ask why, as air is a measurably homogeneous gas, 1 cubic foot which chances to have acquired heat should retain its identity and displace another cubic foot of air which happens to have remained cold? To press this question might be "to inquire too curiously." The author says:

Hot air, then, is not lighter than cold air. If, however, 1 cubic foot of (any old) air is heated and in expansion made to fill 2 cubic feet, each resultant cubic foot weighs only one-half the weight of the original cubic foot, because it contains only one-half as much air. The same amount of air, however, now occupying 2 cubic feet, weighs as much as it did before it was heated.

This is indisputably true, and would be interesting and significant if 1 cubic foot of air was different from another foot of air, and had a distinct and inextinguishable identity. But it hasn't. It leads us irresistibly to the conclusion that a cubic foot of warm air weighs (or may weigh, if hot enough) only half as much as a cubic foot of cold air. That it is acted on by gravity, and that in consequence of such action it tends downward instead of upward, is true enough, but so for that matter does a cork in water. The reason the immersed cork floats, while the cork in air lies quiescent as near the center of the earth as it can get, is because it is lighter than the water it displaces in the one instance, and heavier than the air it displaces in the other instance. Light and heavy are relative terms.

In splitting hairs as to the meaning of words, Professor Gager appears to have lost sight of the fact that too much refinement of one's technical vocabulary is apt to result in a confusion of ideas. As an abstract scientific proposition it is not true that hot air tends to rise.

It is true, however, that in a body of air of unequal temperature the parts which are warmer, being lighter, volume for volume, than the parts which are cooler, do rise, not by virtue of what the old physicists called "specific levity," but because gravity, acting more powerfully on the denser air, draws it down and deposits it in strata under the warm air, which is thus uplifted and made to assume a relatively higher position.

Consequently, to say that warm air, which does rise relatively to colder air, which is more powerfully acted on by gravity, because more dense, has a "tendency to rise," is to state the fact correctly—within the usual limits of colloquial accuracy. Relatively in cold air, hot air rises. It does so in obedience to a natural law, which compels it to do so. What matter is compelled to do in obedience to natural law it tends to do. What matter tends to do habitually may, without a very violent stretch of the imagination, be said to represent its tendency. The phrase may not reflect all the shades of meaning which present themselves to the mind of one who is both a physicist and a purist; but it is a long way from admitting of proper classification among the "errors of science teaching." I am accordingly compelled to conclude that Professor Gager, in this instance, has found against the familiar phrase, "Hot air tends to rise," an indictment which will not stand, and which must be dismissed with costs—said costs having been incurred in the publication of his entertaining little book.

Another familiar formula which Professor Gager seeks to discredit by showing that it is fallacious and misleading is that

HEAT EXPANDS AND COLD CONTRACTS.

The several pages of his unique book devoted to demolishing this familiar axiom are full of interest, but they lead to the conclusion that it would be perfectly satisfactory if recast as follows: With two known exceptions, masses of matter when heated increase in bulk for the reason that the molecular movement, becoming more energetic with each degree of absorbed heat, demands that the molecules have more room in which to oscillate. Hence the dimensions of such mass of heated matter become greater, and we observe the phenomenon popularly known as expansion. If, however, the temperature of the mass is lowered the attraction of cohesion tends to re-establish the molecular relation temporarily disturbed, and we observe the phenomenon of contraction erroneously attributed to cold, since the body shrinks.

This would be very good phrasing for the class room or the lecture platform; but life is short, and let us see whether any essential error is embodied in the familiar formula, "Heat expands and cold contracts." Let us suppose that 60 degrees F. is our datum line. It is probably as near to average normal temperature as we can get. Indoors we have a stove, out of doors the thermometer records zero. The object of our experiment is a rod of iron. If we take this to the stove and leave it where it will become hot we may, if we know how and our instruments are delicate enough, establish the fact that with each degree of heat taken up by the iron above 60 degrees F. the rod expands sufficiently to add 0.00006 to its length. If, on the other hand, we take the rod at 60 degrees F. and lay it on the window sill, we may, by the same methods, observe that it contracts sufficiently to shorten it as much for each degree of heat lost as it lengthened with each degree of heat added.

Half the proposition is certainly true; the other half is in error only in the assumption that cold is a force, the antithesis of heat, whereas it is simply a phenomenon resulting from the absence of heat. Strictly speaking, cold does not contract—it is the attraction of cohesion which does that; but the student might very well reason as follows: "Cold is a term employed to indicate the absence of sensible heat; ergo, the absence of heat is cold. Matter expands by reason of the presence of heat; in the absence of heat it contracts again. Hence heat expands and the absence of heat permits contraction. To save time I will express this phenomena in the simplest and most intelligible language I can employ—viz., heat expands and cold contracts. If the Professor

should quarrel with my terminology, I will tell him that I know perfectly well that cold is not a force and don't contract things, but that I really believe I can employ my time to better advantage in learning phenomena than in lying awake nights wondering how to describe them in words of such precision that a hypercritical old pedagogue cannot find opportunity to correct them. When I become a teacher it will be time enough to subject every word employed to a qualitative and quantitative analysis."

Still another popular scientific error upon which Professor Gager jumps—I was about to say with all four feet, but, as he probably has only two feet, I might thereby lay myself open to correction—is the statement that

WATER SEEKS ITS OWN LEVEL.

This sentiment, Professor Gager insists, has no meaning, since water does not seek anything. Technically, this is correct. The habit of indulging in or prosecuting searches is not one of the attributes of water. It flows, percolates, permeates, evaporates and does an infinite variety of things, but it does not search. Perhaps this is due to the fact that it does not know just what it wants, and consequently cannot look for it. Professor Gager's thesis is that water has no "level" of "its own," which it continuously seeks. It is not difficult to establish this thesis. If one makes a man of straw he may buffet him, abuse him and end up by kicking the stuffing out of him, and be quite sure he will meet no formidable resistance and suffer no reprisals. A translation of the objectionable formula that water seeks its level would be that water in vessels between which communication exists will, if unrestricted by adverse and disturbing influences, ultimately stand at a common level in both. In this form it is unobjectionable. Professor Gager interposes the objection, however, that if a number of stand pipes are erected perpendicular to the horizontal outflow pipe of a reservoir in which water stands at the level of, say, x , the water will not rise in these stand pipes to the level x , but that the levels it will attain in the stand pipes will correspond to a line drawn from x , the level of water in the reservoir, to o , the orifice of the discharge pipe—presuming, of course, that the orifice is open.

I presume this is so, but inasmuch as the water is diverted from its natural tendency by reason of the fact that what it might like to do is incompatible with what it must do under the circumstances described, it is not exactly clear to me that the phenomenon described establishes the fact that the "tendency" to rise in the stand pipes to the level of the reservoir does not exist. I have frequently found my own tendency thwarted by adverse circumstances, and have been unable to do what I wanted to do by reason of the fact that I could not do it. This may be the case with the water. If the orifice of the discharge pipe is closed the rapidity with which the water will rise in the stand pipes to the x level of the water in the reservoir will be found extremely suggestive of a previously restrained tendency on the part of water to do this very thing.

To say that "water seeks its own level" is a loose way of expressing a perfectly well understood phenomenon, but it is about as brief and convenient a form of words as could well be found. It implies that part of a body of water has been temporarily elevated or depressed above or below the level of the rest of the same body, and that, if free to move, it will return to its place as part of such larger body and the common level of the surface of such body will be as promptly as possible restored. This statement of the matter is indisputably true. It is also true, as exemplified in the hydrostatic paradox, which bothered the early philosophers from Archimedes down, that if two bodies of water, one as large as the Atlantic and the other inclosed in the bore of a pipe stem, are connected, the water will stand in one exactly as high as in the other.

The more we study Professor Gager's little book the more we wonder why he wrote it. However, if others have as much pleasure from it as I have had, it will not have been written in vain.

The Hubbell Riveting Machine.

The new riveting machine manufactured by Harvey Hubbell of Bridgeport, Conn., will take work up to 3-16 inch. The foot lever is connected with a bell crank, which operates a hardened steel bolt, pushing it under the hammer spindle at the top of the stroke, stopping the machine instantly. The hammer is caused to rotate by a ratchet device that operates on the up stroke. The spindle strikes about 900 strokes per minute. The blow is adjusted by changing the tension spring on the hammer spindle. The table is adjustable by being clamped on a gibbed way, and is rigidly held in place by a piece of metal inserted in horizontal grooves planed in the

The Hubbell Riveting Machine.

pedestal, and has no chance to jar down. The weight of the machine with countershaft is about 300 pounds, the height being 60 inches and the floor space 20 x 12 inches.

Adulterated Linseed Oil.

The adulteration of linseed oil is becoming a common practice among small dealers, both in New York and other cities, in spite of many arrests and fines, says the *New York Commercial*. The State Department of Agriculture has a bureau for the inspection of oils in Albany and its agents are frequently sent to New York to inspect the oil shops. Frequently spurious oil is found, and a fine of \$100, the State penalty, is paid.

The Government inspector takes two samples of the oil. One he seals and leaves with the dealer and the other he takes with him for analysis. In case of a dispute or if the matter is carried into court, the first sample is turned over to a chemist for his opinion. The spurious oil is sold as pure stock, and frequently the barrels of prominent crushers have been used.

It is reported that a suit for damages will soon be filed against a jobber by a well-known oil manufacturer.

There are only six States where stringent laws against the adulteration of linseed oil exist. They are New York, Pennsylvania, Michigan, Ohio, New Jersey and Illinois. The recent high price of linseed oil was a great temptation to unscrupulous dealers to increase their supply of linseed oil, by mixing with it neutral oils. These facts became known on account of these firms underselling the crushers and the many complaints entered by consumers.

Among the oils used for adulteration are corn, cottonseed, petroleum and other mineral oils.

The Cooling and Warming of Closed Air Spaces.*

BY PROF. DR. RECKNAGEL OF AUGSBURG, GERMANY.
Translated from the German by Charles F. Hauss.

In his well-known work on heating, "Leitfaden zum Berechnen und Entwerfen von Lüftungs und Heizungsanlagen," page 111, Professor Rietschel says: "In general practice it is during the period of continuous heating only that the absorption of heat (by the walls) is considered as being worthy of thought. In the absence of a good rule we must depend on results as a guide." I would be pleased to help overcome this lack of theory. Literature has thus far brought nothing of service. The problem given in 1822 by Fourier in his celebrated "Theorie Analytique de la Chaleur" was not solved by him nor has it been solved by any one since. Yet Fourier's works offer a good basis for figuring.

The nature of the problem leads, first of all, to studying the process of cooling. I will not weary you with the complicated formula and equations necessary for solving this problem, but will eventually prepare tables, with the help of several young mathematicians, that will illustrate what can be done with this new theory.

RESULTS.

What interests us most are results, and

- 1. The temperature of the inside air = J.
- 2. The temperature of the wall inside = Ti.
- 3. The temperature of the wall outside = Ta.

The following results were obtained by assuming a room 16 x 16 x 13 feet, with a single exposed wall 16 x 13 feet = 208 square feet, exposed to free air of - 4 degrees F., and the temperature of the inside air of + 68 degrees F. at the start, and that after shutting off the source of heat the room was left to cool. The exposed wall is of brick with a specific weight = 1.8, calorific capacity = 0.2 and conductivity = 0.7.

Two thicknesses of wall were considered, the one 10 inches, the other 20 inches thick, and each was used once in still weather, and once in windy weather, and in

The Cooling and Warming of Closed Air Spaces.—Fig. 1.—Curves Showing the Process of Cooling Indicated in Tables I and II.

the latter case the velocity of the wind was 16 to 20 feet per second. In each case the result is shown in one, two and ten hours of continuous cooling:

I.—With 10-Inch Wall.								
Time.	Inside air, J.		Inside of wall, Ti.		Outside of wall, Ta.			
	Still.	Windy.	Diff.	Still.	Windy.	Diff.	Still.	Windy.
Beginning...	68	68	0	51	46	5	13.5	0
After 1 hour.	46	41	5	46	39	7	13.5	0
After 2 hours.	42	36	6	42	35	7	13	0
After 10 hours.	28	19	9	28	18	10	10	-2

II.—With 20-Inch Wall.								
Time.	Inside air, J.		Inside of wall, Ti.		Outside of wall, Ta.			
	Still.	Windy.	Diff.	Still.	Windy.	Diff.	Still.	Windy.
Beginning...	68	68	0	57	55	2	+7.5	-1.5
After 1 hour.	53	51	2	53	51	2	+7.5	-1.5
After 2 hours.	51	49	2	51	48	3	+7.5	-1.5
After 10 hours.	42	38	4	42	38	4	+7.5	-1.5

LOSS OF HEAT IN TEN HOURS.

Because of the evenness of the temperature of the outside wall the heat losses to the outside air continued while the cooling process was going on in the same ratio as during continuous heating. The largest difference was shown in still weather with the 10-inch wall, when 46,460 heat units were lost during ten hours of heating, while 43,552 heat units were lost during ten hours of cooling. Even this small difference of 7 per cent. disappeared in windy weather, when, in ten hours, about 58,000 heat units were lost, whether we continued to heat or al-

lowed the space to cool. With the 20-inch wall there was hardly enough difference worth mentioning, as there were 30,580 heat units lost in still weather and 35,580 heat units lost in windy weather.

HEATING

Having shut off the heat, we must sooner or later arrange to heat the room to make it habitable. If, for instance, a room that has been allowed to cool over night in, say, ten hours, should be warmed in two or three hours, then the question arises, How much heat must be brought in?

To illustrate this, the theory was tried on the room with the 20-inch wall, the outside temperature being - 4 degrees F. in windy weather. After ten hours of cooling the inside air had a temperature of 38 degrees F., the

Fig. 2.—Curves Showing Temperature at Different Depths of a 20-Inch Wall.

inside surface of the wall also 38 degrees F., and the outside surface of the wall was - 1.5 degrees F. This was the state of affairs at the beginning of the period of heating.

The intention being to restore the temperature of 68 degrees F., to do this we would require for a difference in temperature of 72 degrees F. 3520 B. T. U. in windy weather, to which, according to Recknagel's Kalender, we must add for periodical heating 20 per cent.,* which will be confirmed as correct if we come near the mark in two hours. To this I add 25 per cent., which is customary when the exposed wall points north, northwest or northeast, as I do not intend to depend on the warmth of the sun to help. Hence, there is in all 45 per cent. to be added, according to which we need 3520 x 1.45 = 5104 B. T. U. of heat to be supplied per hour, giving the following temperatures:

III.—Heating.			
Time.	Inside air, J.	Inner side of wall, Ti.	Outer side of wall, Ta.
Beginning	38	38	-1.5
After 1 hour.....	63	44	-1.6
After 2 hours.....	65	47	-1.7
After 3 hours.....	68	49	-1.8
After 10 hours.....	74	55	-2

After a long time of continuous heating we will have, with the same amount of heat supplied, the following temperatures:

	Inside air, J.	Inner side of wall, Ti.	Outer side of wall, Ta.
After x hours.....	86 degrees F.	70 degrees F.	-2 degrees F.

This shows that even though the inner air temperature is raised very rapidly, that of the inner surface of the wall rises very slowly.

After two hours of heating the inside air temperature is not far from the required 68 degrees F., but the inside surface of the wall, which has a known influence on the comfort of the tenant, is more than 7 degrees F. colder than in a room that, having been heated to 68 degrees F., only reaches this temperature (55 degrees F.) in from nine to ten hours.

After three hours the room has the required temperature of 68 degrees F., yet the inner surface of the wall is

* Rietschel says, add 28 per cent. if the room is to be heated in two hours, and 19 per cent. if it is to be heated in three hours in periodical or interrupted.

still 6 degrees colder than it would be after a long period of heating. The outer surface of the wall continues to lose heat, and does not seem to feel the changed conditions on the inside; the amount of heat lost to the outer air is more than is gained from the inner air.

The diagrams presented in Figs. 1, 2 and 3 show in curve form what is shown in the tables in figures.

Fig. 1 illustrates the process of cooling, as shown in Tables I and II. The horizontal lines indicate the temperatures, and the vertical lines the time. Of the curves, the upper one is for a 20-inch wall in still weather, the second for 20-inch wall in windy weather, the third is for 10-inch wall in still weather, and the lower one for 10-inch wall in windy weather.

Fig. 2 shows the temperatures at different depths of the 20-inch wall.

Fig. 3 illustrates the process of heating, as shown in Table III. The curve *a* shows the inner air temperature,

Fig. 3.—Curves Showing Process of Heating Indicated in Table III.

and the dotted vertical lines to the left of the center line *b* show the time, the center line being the beginning, and then one, two, three and ten hours later. The vertical center line *e* is the inner surface of the wall, and the right-hand vertical line *c* is the outer side of the wall.

STOPPAGES IN PIPES.

BY LISTENER.

It is not uncommon for the heating or plumbing system of a building to give trouble from improper piping or bad workmanship, and it requires, in some instances, a rather broad knowledge of the principle involved in the work to locate the cause of the trouble and apply a remedy. Three cases of stopped pipes have recently been brought to my notice which it may interest the trade to hear about. A large heating contracting house who made a specialty of a particular class of work received a contract from a good customer for the heating of his own residence. Naturally, it was desirable that everything reasonable should be done to give this customer a good and satisfactory job. The workmen in charge were instructed to be careful in all the details of the work, and the job was finished during the summer. After its completion the coal bins for the heating apparatus and for the kitchen fire were filled with fuel nearly to the ceiling. When the winter came on the plant was fired and shortly the complaint was received that a portion of the building could not be heated. Immediately workmen were sent to see what caused the trouble. Some insignificant changes were made without relief, and a visit was necessitated from one of the firm, who had served his time regularly as an apprentice and pipe fitter. On reaching the cellar he found a long pipe ran along one wall toward the portion of the building which was not properly heated. This pipe made a turn before reaching the risers to the unsatisfactory radiators. He immediately inquired whether this pipe had a pitch all the way to the risers, so that any air that

might accumulate in the pipe could escape through the risers. He was assured by the workmen that this pipe was all right. Notwithstanding the darkness in the cellar, and the fact that the coal in the bins nearly reached up to the pipe, he was satisfied that the trouble must be at a point where the pipe made the turn. It was only after he had applied a level to the pipe and crawled along over its entire length that he discovered that the pipe ran up to the point where it made the turn and down from that point to the riser, and that this method of piping allowed sufficient air to accumulate in the bend to fill the pipe entirely. The workmen naturally were discomfited and the inspector somewhat exasperated. It simply required an adjustment of the pipe hangers to preserve a perfect pitch throughout the line of pipe, when there was no further trouble.

In another instance a heating contractor and all of his workmen had endeavored unsuccessfully to locate the cause of the trouble with the heating system, and a heating engineer was employed to discover the cause of the failure. The plant was equipped with a water feed regulator and a damper regulator. When the expert arrived on the spot he opened the feed door to allow the fire to cool down, and then fired again and watched the operation of the plant and its appliances. Finding that the damper regulator acted in a peculiar manner, he began a study of the piping, and finally deciding that the failure to heat and the peculiar operation of the damper regulator could only be caused by a stoppage in one of the pipes, he stated that a certain pipe was stopped. Such a positive assertion was met with an equally positive doubt on the part of the heating contractor and his employees, but as there was a union on this pipe the union was disconnected and the pipes sprung apart, a wire being pushed into one end, showing that it was clear, but on inserting the wire in the other piece it encountered a wooden plug. Further investigation showed that when the damper regulator was attached it did not operate, owing to the failure of the workmen to understand how to connect it properly, and they had discovered that by stopping this pipe the damper regulator would work, and with no consideration for the consequences to the operation of the entire heating plant the pipe was stopped in order that the damper regulator should work properly.

In another case a plumber was called upon to find why it was impossible to draw water from one part of a system of plumbing which had recently been completed with lead pipe. After a number of experienced workmen had inspected the piping and stated that there seemed to be nothing wrong, a young workman of a studious nature and inquiring turn of mind was sent at the urgent request of the owner to satisfy the complainant for a time, without supposing that the trouble would be located and remedied. The young plumber knew that if pipes were open in a plumbing system, where there was a good pressure of water, nothing could hinder water flowing from the faucets on any part of the system when the faucets were open, and decided to take along with him his metal pot and wiping kit. His visit to the owner resulted in an inspection, carried on in a similar manner to that of those who had inspected before him. The owner took him through the building and he viewed, with his hands in his pockets, all of the different pipes, paying careful attention to all of the wiped joints that the numerous pipes required, owing to their length. One wiped joint excited his suspicion as to its being perfect. It did not differ materially in appearance from others, yet it had a peculiarity which attracted the attention of the young plumber. He explained to the owner that he believed that in wiping that particular joint the pipe had been burned and that the pipe was full of solder, and at his suggestion the water was shut off. He then cut out the joint, and, as he suspected, found that the pipe had been burned through and was filled with solder. Then, by loosening the tacks which supported the pipes and pulling on the ends, he succeeded in stretching the pipe enough to bring the ends together so that a new joint could be wiped. After preparing the joint and wiping it, the water was turned on to the building and there was no further trouble in drawing water from the faucets.

SOIL PIPES.

The following comments of a special contributor to the *Decorators' Gazette and Plumbers' Review* of London on the material selected for soil pipes by the authorities there will be of interest to the plumbing trade:

The recently published by-law of the London County Council on drainage, by which soil pipes may be fixed inside of new buildings, but stipulating that in the event of their being so fixed they shall be of lead, calls prominently to mind the different opinions held in England and America on this subject.

Any one who understands plumbing and is possessed of a sense of humor can always enjoy himself by reading the opinions of writers on this subject. Whether the writer be English or American he has no hesitation in expressing his views. There is no room for two opinions. Each one knows all that is worth knowing on the subject, and opposite views are treated with deserved contempt.

One English writer says, "It ought not to be necessary to say a word on the material of which soil pipes should be made; but as there is a tendency in some quarters to use cast iron, it may be well to look at this matter and see what advantages lead has over iron. Lead soil pipe is smoother and cleaner in its action than cast iron pipe, and is therefore more wholesome; and, being of a closer texture, it is not so corrosive and is consequently more durable. Then the joints and connections of lead soil pipes are more to be depended on. . . . Lead pipes will stretch without breaking their joints in the case of a little sinking of the building."

And again, "In seamless lead pipe for soil pipe the plumber rejoices in the use of a pipe which for soundness, wholesomeness, durability, compactness, appearance and the reliability of its wiped solder joints . . . is, as proved by experience, superior to earthen ware, stoneware, zinc, copper, cast iron or wrought iron pipes."

The same writer insists on seamless or drawn lead soil pipe, as he acknowledges a danger from the seams of hand made pipe. In what respect the danger arises from a soldered seam, seeing that the soldered joints are absolutely reliable, the writer does not explain.

Another English writer says, "Undoubtedly lead is the material given us for soil pipes." He advocates hand made pipe, as sheet lead is so much purer. Zinc and other impurities enter largely into the substance of drawn soil pipes. Again, it is very difficult to get drawn soil pipe with an even thickness all around. Most of it is thicker at one side than the other. Even if the thickness is regular at the ends, it is not so throughout its length. He adds, "It is all fudge about good soil pipe giving way at the seams."

Yet another Englishman writes, "There is no better material for soil pipe than lead." It is neater, takes up less room, can be bent to suit any position. It is smoother inside and therefore a pipe of the same size will pass more water in a given time. Or, to pass a given quantity of water a less pipe can be used. Cast iron is only used on account of its cheapness.

A Scotch writer does not deal with the question directly, but assumes the soil pipe will be of iron, and points out that lead needs repairs and renewals from three causes—putting in pipe of too light substance, improper fixing and corrosion, the latter due to want of ventilation.

An Irish writer says, "The best material for soil pipes is undoubtedly drawn lead piping. It possesses the qualities of smoothness of surface, freedom from corrosion, pliability in bending, security in jointing and value of old material when worn out." The last is somewhat of a favorite argument.

One American writes, "The advantages of cast iron over lead are many. In the first place it is cheaper; but its chief superiority lies in its being lighter, stiffer and stronger and less liable to accidental injury. Thin lead pipe of large diameter is necessarily weak, while thick lead is too heavy and too costly for use. Lead is difficult to fix. We could scarcely wish for a better material than iron. It is so easily cast into any desired shape."

Another American says, "I shall not dwell upon the well-known defects of lead soil pipes; although still the rule in England, they have, fortunately, in this country, become a thing of the past, and when found, upon examination of houses built years ago, are invariably condemned and removed."

The same writer says, "Tarred or enameled iron pipe is fully as smooth as lead pipe, and the iron pipe is thereby well protected from corrosion. The large variety of special fittings enables the plumber readily to adapt his iron pipe to almost any position; iron pipe should not take up a great deal more room than lead pipe of the same bore. Well calked joints of heavy cast iron pipes and well made screw joints in wrought iron pipes are just as sound and trustworthy as wiped joints in lead pipe, and any good mechanic is able to make them. Urine does not

corrode an iron soil pipe, protected by a coal tar pitch solution or by enamel, more than a lead pipe. The outside of iron pipe can be efficiently protected from rusting by paint, coal tar pitch or enamel. But while iron pipe is fully equal in all respects to lead it has great advantages over it. Lead soil pipes are very heavy, and, therefore, liable to sag and split open, to have holes eaten into them by rats and have nails driven into them by carpenters, and also to corrode, and they require much greater skill to put up, and involve more expense; therefore, the statements made in favor of lead prove nothing, although they demonstrate the absurdity of bricking soil pipes into a wall, and the necessity of so placing them that they are at all times readily accessible for inspection, and also prove, what few people seem to realize, that the drainage system of a house requires periodical testing and inspection just as much as a steam boiler or piece of machinery."

Again, "The use of wrought iron for soil pipes is of a more recent origin than cast iron. In the Durham system of house drainage wrought iron is used exclusively for all pipes above ground, whether drain, soil, waste, leader or air pipes. By using the standard wrought iron lap welded coated steam pipe in works of house drainage one great desideratum is easily attained—i. e., tight joints; for screw joints in steam pipes can easily be made sufficiently tight to stand a heavy internal pressure, such as, for instance, the pipes are subjected to by testing them with a force pump and a manometer, or by the water pressure test. Another advantage wrought iron pipe offers is the lesser number of joints required. For steam pipe comes in lengths up to 20 feet; it can be cut according to measurements so as to run from floor to floor without intermediate joints. A further point in favor of such pipe is its uniform thickness, its great strength and the fact that every length is tested at the mills by hydraulic pressure."

It is somewhat surprising that all the writers on one side of the Atlantic should unanimously come to one conclusion, and all the writers on the other side be as unanimous against it. It is possibly due to the fact that all the British writers are master or foremen plumbers, while the Americans are civil engineers. The former approached the question with a trade bias as well as the usual British conservatism. The latter were not so hampered in looking for a solution, and cared not how revolutionary the change might be.

The sanitary problem was tackled in both countries about the same time. The dangers of defective plumbing were recognized by both. Old lead soil pipes were found by both to be perforated by corrosion at their upper parts, allowing bad smells and dangerous gases to escape.

The English condemned the want of ventilation, and, as an added precaution, when renewing soil pipes placed them outside the buildings. The Americans condemned the lead and as an added precaution ventilated the soil pipes.

The Americans, on account of the climate in the Eastern, Middle and Northwestern States, could not place the soil pipes outside. They therefore made drastic by-laws—which they call city ordinances—and appointed plumbers as inspectors to see the by-laws enforced. The drain when in or under the cellar of a house is also called the soil pipe, and is of the same material, so that, as plumbers say, "The soil pipe extends from 2 feet outside the front wall to 2 feet above the roof."

Having decided on the best material of which to make soil pipes, each writer appears to think it necessary to depreciate the material so chosen on the other side of the ocean.

Experience gained as a sanitary inspector certainly indicates heavy iron as the best material for inside soil pipes. During the inspection of one of the largest hotels in London, when a chemical test was applied to the soil pipes, several, which were inside the building, were found to be defective. On examination one, which passed near the kitchen, was found to have connected with it the waste pipe from a kitchen sink. The hot water occasionally passed down the pipe and buckled it out of shape, and in two places the pipe was broken. In one of the bedrooms, where the test gave a result, on removing the casing, chisel marks and cuts were found. In another bedroom nails had been driven through the pipe. In another business establishment, on uncovering the soil pipe, in consequence of it having been condemned, it was found to be perforated with nails.

In the basement of a school some water closets were fixed, connected directly with the drain. Some years afterward alterations were made, and in taking down the partition between two closets it was found that one of the plugs driven into the wall as a fixing for the partition had been driven right through a soil pipe built into a chase, and into the joint in the brick work behind it.

None of these accidents could have occurred if the soil pipe fixed inside the buildings had been of iron.

St. Louis Master Plumbers.

The annual meeting of the Association of Master Plumbers of St. Louis, Mo., was held in the Century Building on December 16. After hearing the reports of the officers and transacting the usual business, the following officers were elected for the ensuing year:

President, James P. Carroll.

First Vice-President, John F. Reardon.

Second Vice-President, P. H. Callahan.

Treasurer, A. F. Fetting.

Corresponding Secretary, J. F. Corrigan.

Financial Secretary, O. B. Hervers.

Sergeant-at-Arms, A. L. Kiel.

Conference Committee: H. D. N. Doerner, P. J. Whelan and William Norris.

Auditing Committee: John M. Peters, John Frost and William Norris.

Sanitary and Heating Goods in Russia.

A contributor to the *British Trade Journal*, in an article on openings for the introduction of British manufactures into Russia, has the following to say in regard to the market in that country for sanitary and heating goods:

SANITARY APPLIANCES.

A highly important opening for a large class of manufacturers in England has been recently created by the efforts which the Government, aided by the *Zemstva* in all the more important provinces, are now making for a reform in sanitary matters. I can here only indicate a few important facts which intending exporters should bear in mind. The physical difficulties to be encountered in Russia are mainly due to the climate and geographical position, and a Russian architect, holding a highly influential position, informs the writer that a large fortune awaits the man who can succeed in overcoming them.

In the great majority of the provincial towns the houses are absolutely unprovided with any sanitary installation. This condition of things is distinctly contrary to the law, which is now being more strictly enforced. The difficulties in the way of reform are, however, considerable. In the smaller towns there is often practically no drainage system, and even in the larger it is extremely imperfect. The expense that improved systems of drainage would entail, if organized as they would be in England, would be altogether beyond the means of the local authorities at this moment. Besides this, even where some sort of drainage exists, the uniform flatness of the country as a rule, and the absence of an effective water supply, immensely increase the difficulty of flushing the drains during the six months of winter, when the ground is frozen to a depth of over 3 feet. From this it will be seen that, except in the larger towns, the use of any closets in which water is the sanitary agent is entirely impracticable. Systems in which earth, ash, or some similar inexpensive substance can be employed are what are needed, but no appliances fully meeting the Government requirements have as yet been brought forward. Cheapness and simplicity in construction are absolutely essential. The same physical difficulties in connection with drainage have led in many quarters to a growing demand for some effective system of "destructors" for household and street refuse, which could be employed in the smaller towns.

STOVES.

The question of fuel is now one of considerable difficulty in a large part of Russia, not only in factories, but for domestic purposes. Notwithstanding the immense forests in the north and east, the total area of woodland in the rest of the country is not proportionately larger than in France, while in a large part of South Russia it is actually smaller than in England. As wood for fuel cannot be conveyed for any considerable distance, petroleum for cooking purposes is now very largely used, and there is an immense demand for cheap and practical stoves for household use. There is also an enormous market for the cheapest descriptions of petroleum lamps. These are now chiefly supplied by Germany, but many of the cheaper kinds are so dangerous in their construction that in several Governments their sale is prohibited. In Russian villages, in which the *izbas* are constructed of resinous pine timber, crowded together and straw thatched, a single dangerous lamp is a peril to the whole community. Perfectly safe petroleum lamps or lanterns, of a price within the purchasing power of the peasantry and the poorer classes, would be sure of an immense sale in Russia, where the risk of loss of life and property by fire is an ever dreaded danger.

In those districts in which wood for fuel is practically unobtainable, charcoal, which can be more easily transported, is now being extensively used. The charcoal stoves are of many different kinds. The portable ones, resembling those in use in France, are imported from Belgium. Peat is also largely employed over the greater part of Russia, and a new and very practical form of stove, specially adapted for this fuel, has recently been introduced from Germany.

Water Waste and Its Causes.

The city of Montreal has been investigating the uses made of the city's water supply, says *Municipal Engineering*, and finds many which are unauthorized and not paid for. Meters are inserted with great benefit to the city's revenues, first in cash payments for water used, and later in reduction in use of water formerly not paid for. The last report of Superintendent Janiu covers a period of 12 months ended October 31, during which time 36,066 dwellings were inspected and 2550 defective fittings were discovered, which wasted on estimation 43,562 gallons of water each hour. Supposing these fittings were out of order for a fortnight it would mean a waste of 15,000,000 gallons of water, which at the cost price of 8½ cents per 1000 gallons would cause a money loss of \$1300.

This simple process of calculation serves to explain how great must be the annual loss which the city suffers from the distribution of water. The report draws attention to the impossibility of discovering all the leakages, but declares that the moral effect must far surpass the actual money saved, which in cold figures would mean the difference between \$3707 collected and \$3482 paid out in wages for the inspectors.

A few examples show the character of cases discovered by the inspectors:

Inspector Kelly discovered an unmetered service pipe, running into a tannery. In two weeks a meter put the indebtedness at \$10.

Another proprietor got into the habit of pumping his cellar dry without paying for it. A meter was installed, and the account became \$154 at the end of the year.

The proprietor of a dining room kept his guests cool by using two fans. One day a civic inspector was hungry and he entered. Before he came out a water meter was ordered, for the working of which the city drew \$8.

Even an electric power station wanted its water free. The buzzing machinery made the management forgetful of its obligation to the city for using the water to cool the heated bearings and boxes. The account was metered at \$203, representing the cost of three arc lights for a whole year.

Inspector Salmon noticed a ginger ale manufacturer was using too much water for the good of his trade. A meter showed he was a debtor of \$30.

Inspector Whelan rated a large number of steam engines, and incidentally found six which were not rated at all, and the civic revenue grew by \$260.

The city of Evansville is discussing meters as a means of cutting the waste out of its present supply of 167 gallons per capita per day, especially since it will soon be necessary to install a filtration plant. The experiences of Montreal will doubtless be paralleled when the services to which meters should be applied are searched for.

Heating and Plumbing Notes.

THE AMERICAN TUBE & STAMPING COMPANY, who recently acquired the business, plant and good will of the Wilmot & Hobbs Mfg. Company of Bridgeport, Conn., are contemplating improvements which will greatly increase the output of the plant of that concern. There is said to be a likelihood of the works being removed from Bridgeport in order to secure better facilities, but no definite decision on this point has yet been arrived at. The plans for extension include the building of an open hearth plant with a capacity of from 200 to 300 tons of steel per day. At present the Wilmot & Hobbs plant is dependent upon the open market for a supply of steel billets. The capital stock of the American Tube & Stamping Company is \$2,800,000.

The plumbing establishment of John I. Kopp, at Boonton, N. J., was destroyed by fire last week.

THE ALLEN & VAN NEST COMPANY, 82 Centre street, New York, have the contract for installing a new heating apparatus in the Reformed Church, at White House, N. J.

THE HAWAIIAN SUPPLY COMPANY of Honolulu, H. I., have favored us with a copy of the special industrial edition of the *Evening Bulletin*, published in their city. The paper gives fine half-tone illustrations of many of the plantations, from which it will be readily seen that the steam fitter could find plenty of work in installing power plants and the plumber be busily occupied in arranging for a water supply.

THE PENINSULA HEATING & PLUMBING COMPANY of Calumet, Mich., have the contract for installing the heating apparatus in the Douglass House, at Houghton.

THE City Council of Los Angeles, Cal., are considering an ordinance to do away with fees for plumbing permits and to provide for licensing plumbers upon a varying schedule, ranging from \$25 to \$40 a year for a license.

J. H. LAWLESS, 131 Third street, Jersey City, N. J., reports an active demand for his patent Plumbers' Force Pump, a shipment of these Pumps having recently been made to the Navy Department of the United States. The Pump is so constructed that it will act either as a suction Pump or a force Pump, and a high pressure can be raised with it. The metal from which the Pumps are made is said to be capable of standing a pressure of 1000 pounds.

THE NATIONAL STEAM ECONOMIZER COMPANY of Springfield, Mass., bid \$8293, and were awarded the contract for heating the new Chestnut Street School in that city.

BLAKE & ANDROS, 28 Portland avenue, Boston, Mass., are sending out, with their good wishes for the season, a wall calendar 12 x 18 inches in size, advertising their B. & A. Elbow Valves and Crescent Hot Water Heaters and Steam Boilers. The monthly calendar tablets which are attached to the bottom of the hanger have the dates clearly printed in bold lettering, and the sheet is provided with a brass eyelet, making it handy for hanging upon the wall.

NORRISTOWN COVERING COMPANY, Norristown, Pa., are sending out a catalogue showing their Steam Pipe and Boiler Coverings, Asbestos Cements, Sectional and Block Coverings, Asbestos Goods, Mineral Wool and Hair Felt.

J. B. CARROLL, 36 La Salle street, Chicago, sent out an illuminated Christmas greeting circular, calling attention to the Hahn Acetylene Gas Burner. This circular is a noteworthy specimen of fine printing and attractive color work.

A FIRE, doing slight damage, visited the plumbing establishment of William M. Anderson, 128 South Twentieth street, Philadelphia, last week.

EDWIN F. PORTER of Boston, Mass., has invented a gas heater for use in connection with electric cooling fans, so as to make these fans serviceable all the year round. When in operation, the fan keeps up a circulation of air in the room, sending a warm current to all parts.

ZIEGLER BROTHERS, Aurora, Ill., sustained a loss of \$1000 by a fire in their plumbing establishment on December 17.

New Firms and Changes.

THE NASHVILLE STEAM HEATING COMPANY have been incorporated at Nashville, Tenn., with a capital stock of \$10,000 by Dr. Joseph P. Gray, J. T. Lellyet, W. A. Stewart, Charles F. Sharp and Edgar Jones.

THE GEORGETOWN HARDWARE & PLUMBING COMPANY, Georgetown, S. C., have been incorporated with a capital stock of \$5000, by S. S. Ingram, Chas. H. Bryan and others.

Telephones in farm risks, says an insurance paper, are likely to have an effect on fire losses of that class, if the plan of a policy holder near Wingate, Ind., is to be followed by others. A fire started in the roof from a defective flue. The farmer immediately telephoned his neighbors, and within a few minutes they began to arrive, on horseback, with teams, and across lots. A

bucket brigade was formed and the fire extinguished with \$200 damage. It is admitted that without the telephone alarm the risk would have been a total loss.

THE ART OF COLLECTION.

BY GENIAL

The most important work of every retailer at this season is getting in the money for goods delivered and work done during the year. Many merchants shrink from asking their customers for money, and there seems to be a very general reluctance, especially among the smaller business men, to go around with their bills.

It is a simple matter, however, to remove this feeling by making these business calls a matter of social pleasure, with the cash collecting feature as an incident. Men who devote all their time to business are apt to frown upon those who have cultivated the genial side of life, and kept themselves informed of all the fads that are dear to the hearts of their townsmen.

This is a wrong attitude, for it stands a man with bills to collect in good support to be able to meet his debtor on common social ground. It is apt to make the debtor feel that if he pays anybody he ought to make an effort to pay a man who has done good work for him and waited for his money in good humor, and who is cheerful in presenting an overdue bill.

No matter how the other man feels, make it a point to show him a friendly spirit when you present your bill. If he hesitates about paying at the time of application, tell him to set a date and say that you will endeavor to keep your creditors satisfied meanwhile. If he names a time, let him know pleasantly that you are depending upon him, as if he was a bank, and then be sure to be on hand at the time set. Of course, in pursuing this method, the books must have been kept up, and all the bills be ready, some to be mailed, but, in most cases, to be delivered personally.

Good humor, pleasant conversation and the evidence of a cheerful conviction that the money will be paid will generally secure, with the invitation to call again, an assurance that then the money will be forthcoming. With those who are haphazard in their financial matters, some discussion of them, with suggestions of how the debt may be gradually reduced, will be welcome, if tact is used.

All men warm to those who show confidence in them, and this confidence should be shown, even if it is felt that it can only be maintained by persistent effort on the part of the creditor to secure payment. There are men who hate to pay out money. But, when their bills are once paid, the friendship and custom of such men are assured if an occasional compliment is made on their reliability as to payment.

Good humor is an important factor in a successful business, whether in making sales or making collections, and it should be especially in evidence in all transactions at this season.

The construction cost of the Pan-American Exposition at Buffalo was \$9,000,000; of the Paris Exposition of 1900, \$10,000,000, and of the World's Fair at Chicago, \$18,000,000. In comparison with these figures the plans of the Louisiana Purchase Exposition, to be held in St. Louis in 1903, indicate that that exposition will far outclass any of its predecessors, for it is contemplated to spend no less than \$30,000,000 in construction work upon it. Moreover, the size of the exposition will greatly exceed that of its immediate predecessors. Its site covers 1100 acres; whereas the Pan-American covered 350 acres and the Paris Exposition only 173 acres.

Says the *Amalgamated Sheet Metal Workers' Journal*: "President Roosevelt has endeared himself to the workman and the friends of organized labor through the manner in which he made reference in his recent message to questions that concern the toiler. He has gone on record as being the first President of the United States to make mention of organized labor in a Congressional message. The views expressed by him on this subject, and others of interest to the worker, are such as inspire confidence."

What Should a Cornice Maker Know?

BY EXPERIENCE.

The answer to the above question seems to be very simple. He should know how to make cornices. But how many cornice makers at the present time are able to construct a cornice complete, from the time the drawing is received from the architect to putting up the work on the building? When one comes to think over the question seriously it is but natural that all cornice makers could not lay out and complete contracts from the scale drawings. An army could not be composed of all officers, but it must have a majority of soldiers. Men are not all gifted alike.

It is not necessary that a cornice maker should know all branches of the work, for in large shops some men do nothing but cutting, others forming at the brake, some put the work together and others set up the work at the building. A man who is an expert at the machine may not be worth one-half his wages when soldering at the bench. Another may be an expert in all branches.

THE ALL ROUND MAN HAS A BETTER CHANCE.

It may seem odd, but it is nevertheless true, that in a large concern the cornice maker of to-day has a better chance of being employed—as pattern cutter, former at the brake, solderer, outside hand or in whatever branch he is most proficient—than in a small shop, where perhaps there are only a few men, who must be proficient in all branches. A cornice maker who thoroughly understands his business from A to Z is the one who will hold his job, while the others are only given work until the rush is over and are the first to be dropped. There are many men who are too old to begin the study required to make them real cornice makers, or learn to read scale and full size drawings and construct any piece of sheet metal work. But there are many young men, who will be the cornice makers of the future, and to whom the writer will give his past experience, which may guide them in their work.

KNOWLEDGE IS POWER.

A cornice maker who can read plans, draw out his details, cut out the patterns, form, solder, put the work together and erect the work on the building is usually the best paid man. Knowledge is power in this and every other trade. By all means let the cornice maker study, so that he will be able to complete contracts from architects' drawings to the erection on the buildings.

The writer laid the foundation of his training by having the good fortune of obtaining employment in a shop where he had a chance to learn. Twenty-five years ago, when ten hours was a day's work, an apprentice had to be in the shop from 6.30 a.m. to 6 p.m.; then clean up shop, which took about one hour, thus returning home about 7.30 p.m., which gave very little time for study. By doing favors and being polite to the men there were many little things learned which proved useful later on. This work from 6.30 a.m. to 7 p.m. lasted during the term of apprenticeship for four years, when another apprentice was taken and an advancement was made, after which the hours were from 7 a.m. to 6 p.m. This gave time for study at home at night.

HOME STUDY.

In the shop tracings of some sketches of cornices were made, the employer always taking an interest in what work was done in this direction. For use at home the writer obtained a small drawing board 16 x 20 inches, with a T square, a 45 degrees triangle and a cheap set of brass drawing instruments, with which the start was made in drawing and pattern cutting, with the help of the shop foreman, a first-class mechanic from the old country. Very little progress was made in this manner, however. The writer then entered the evening classes in Cooper Union in New York.

STUDY AT COOPER UNION.

In justice to that institution, founded by Peter Cooper, let it be said that all the success that the writer has met with in drawing and pattern cutting is due to that

school, where all is free to rich and poor alike. The writer then spent five years in the architectural class, four years in the mechanical class and two years in modeling in clay, two evenings from 7.30 to 9.30 p.m. in each class per week. Thus being engaged for two years every night; for two years, four nights per week and for one year, two nights per week. So thorough is the instruction given that, although the writer had no previous knowledge in drawing, he received the gold prize at the completion of the fifth term in architectural drawing. As before mentioned, these classes are all free, and any ambitious young man can obtain instruction there if he will sacrifice his evening pleasures for study.

WHAT WAS TAUGHT.

The five years of instruction in architectural drawing taught how to thoroughly read plans; the four years in mechanical drawing gave problems in geometry, projections and developments, while the two years in modeling in clay gave a good idea as to how the clay models were made, plastic casts taken from same, &c., which at that time (20 years ago) was required to be known, as ornamental stamping of small objects such as leaves, rosettes, balls, &c., was done in the shop. At the present time this course in modeling in clay could be omitted, as large concerns furnish this stamping cheaper than what it could be made for in a small way.

PATTERN DRAFTING.

After graduating from these classes the writer devoted his entire time, after working hours, to pattern drafting. Any work arising in the shop was noted down, and the drawing and pattern were made at home, using heavy paper bent over the blade of the knife to prove the patterns. The following books also proved of great help: Vere Foster's four books on "Practical Geometry," named "R¹, R², R³ and R⁴," the well-known "Metal Worker Pattern Book," "The Production of Curved Moldings in Sheet Metal," "The Compendium of Architectural Sheet Metal Work," and another book on cornice work by Vaile. As it is sometimes necessary to make small perspective views, the following two books were useful: "Principles on Perspective" and "The Essentials of Perspective."

There is another book, which, though mentioned last, was not the least in importance, and that was a German book on pattern drafting, loaned by a fellow workman. It was written by Th. Raetz, and entitled "Geometry for Tinsmiths, Coppersmiths, &c." In it the methods of triangulation were given. This book was published over 43 years ago in Berlin.

MORE CHANCE FOR STUDY TO-DAY.

Fifteen years ago, through hard study, the writer obtained charge of one of the large shops in roofing, cornice, skylight and sheet metal work, employing between 25 and 30 men, and he still has charge of the same shop. In looking back one can truly say that there is more chance to-day for study and advancement than there was 24 years ago. At that time there were no trade schools, as there are to-day, where a young man could learn in the day time or at night what he fails to learn in the shop.

TRADE SCHOOL INSTRUCTION.

In the class in sheet metal work at the New York Trade School students are instructed for a small sum in cornice, skylight or any other sheet metal work in which they are interested. In this school the student is taught how to use the tools, cut, solder, &c. He then receives blue prints drawn to a scale of different kinds of cornice work, from which he is instructed how to make his full size details, develop his patterns and cut, form and solder the work together at the bench. The evening course requires three years' attendance, while the day course is completed in one year. Each student has his own bench, tools, drawing boards, T square, triangles, &c.

READ AND ASK QUESTIONS.

A young man who wants to keep posted on his trade and in pattern drafting must read trade papers, follow up all articles given therein and by all means ask

questions when in doubt, not only for the information which will be received, but because the question and answer will be read by many more who will profit by it. Give the result of your own experience, because this educates others and stimulates them to do likewise. A good trade paper, with instructive articles and many correspondents, is truly a correspondence school to its readers. If the young men of to-day will make some effort to learn, there will be no asking in ten years from now "What should a cornice maker know?"

WASH BOILER COVER.

A tinner is often called upon to make an oblong wash-boiler cover, having semicircular ends, such as is shown in plan in Fig. 1. These covers are usually made in two pieces, seamed in the center. Let A B C D be the plan

Fig. 1.—Plan, Side View and Diagram of Triangles.

view or shape of the boiler over which the cover is to fit, the semicircular ends being struck from the centers E and F. Through the centers E and F draw the line A C, which bisect or divide into two equal parts and obtain the point G. At right angles to A C and through the points E G and F draw lines, as shown. Now draw the side view of the cover, as shown by H I J. Take the distance from D to G in plan, and place it, as shown, from K to L inside view, and draw a line from L to J, which will give the amount of stuff required on the line B G or G D in the plan. The next step is obtaining the diagrams of triangles used to develop the pattern. Divide one-half of the semicircle into equal spaces, as shown by the small figures 1 to 4, and draw lines to the central

Fig. 2.—Half Pattern of Cover.

point G. Then using G as center and radii equal to G 1, G 2 and G 3, draw arcs intersecting the center line A C at 1, 2 and 3. From these intersections and at right angles to A C erect lines intersecting the base of the cover in side view at 1, 2, 3 and 4, from which points draw lines to the apex J. Then will these lines represent the actual lengths on the finished cover on similar lines in plan. For the pattern draw any vertical line, J L, in Fig. 2, equal to J L in side view in Fig. 1. Now take the distance D 1 in plan and place it at right angles to J L in Fig. 2, as shown by L 1, and draw a line from 1 to J.

Now with J in Fig. 1 as center, and radii equal to J 1, J 2, J 3 and J 4 strike the arcs in Fig. 2, using J as center, as shown by 1 1, 2 2, 3 3 and 4 4. Set the dividers equal to the spaces in the plan in Fig. 1, and starting from the point 1 in Fig. 2, step from one arc to another having similar numbers, as shown by 2', 3' and 4'. In similar manner obtain the points 3'', 2'' and 1'', from which draw a line to J.

Now with 1 L as radius and 1'' as center describe the arc L'. Then with J as center and J L as radius, intersect the arc L', as shown. Draw a line from J to L' to 1'' and trace a curved line through the intersections obtained on the arcs, as shown, which will complete the half pattern of the cover.

Diagram X in Fig. 1 shows the construction of the cover, and the laps which must be allowed to the pattern.

A WOMAN TINSMITH.

At various times the active part that women have played in the different trades in which *The Metal Worker* is interested has been pointed out. There recently appeared in the *Evening Telegram* of New York an article in reference to a woman who has been an efficient helpmeet to her husband, Henry Muskat, who conducts a general tinsmith, roofing and cornice business on Fordham Road, near Jerome avenue, in the Borough of the Bronx, one of the suburbs of New York City. Mr. and Mrs. Muskat came to this country many years ago with but \$24, and they now conduct a successful business in a three-story building, which they own with all of its stock and equipment of tools and machines. Mrs. Muskat took an interest in her husband's work, and acquired the art of handling tinsmiths', roofers' and cornice makers' tools until she became a competent hand in any branch of the trade. She finds time, in addition to her household duties, to do a great deal of work in the shop, and, owing to a press of work at the time their new building was erected, she put on the entire roof herself. Mrs. Muskat is perfectly familiar with all the materials used, and frequently makes trips into the city to purchase stock. She takes a great deal of pride in her handicraft and her ability to work the various machines with which the shop is equipped.

FLASHINGS.

It is reported that the American Can Company will enlarge their Tin Can plant, at Whatcom, Wash., before the opening of next season, and that the changes contemplated will make it the largest establishment of its kind on the Pacific Coast.

The suits which have been entered against the striking Monongahela Tin mill workers at Pittsburgh, who were charged with disorderly conduct and riot during the recent strike, have been quashed, the prosecutors having withdrawn from the case.

We have received from John Plummer of Sydney, Australia, an account of the Iron and Steel works at Lithgow in the Blue Mountain district of New South Wales, in which Steel has been produced for the first time in Australia. An open hearth Steel furnace has recently been added to the plant, and the works also include a modern Sheet mill and a galvanizing plant. Native ores are used in the manufacture of the Steel. It is said that the State of New South Wales abounds in extensive deposits of Iron Ore, much of which is of great richness, and it is likely that the presence of this local metal will tend to stimulate Iron and Steel manufacturing in Australia.

THE DOWMAN MFG. COMPANY, 20 and 22 Trinity avenue, Atlanta, Ga., manufacturers of Galvanized Iron and Copper Cornices, Skylights, Dixie Ventilators and Hot Air Furnaces, have favored us with a copy of an attractive calendar for 1902, which they are sending out to their friends. The calendar, which is 16 x 23 inches in size, is fitted with metal strips at the top and bottom, and arranged for hanging on the wall. It shows a pretty picture in colors of three children, and the calendar proper is printed at the foot of the hanger. The company advises us that they recently secured the contract for the

Sheet Metal work for the new Piedmont Hotel at Atlanta, and also for the Florida State House at Tallahassee, Fla.

WE are advised by Follansbee Brothers Company, Pittsburgh, Pa., that there is no truth in the report which appeared in some papers last week to the effect that they were contemplating the erection of Tin mills.

GUMMEY, McFARLAND & Co., Philadelphia, Pa., have sold a large number of boxes of Pennsylv Old Method Tin Plates, 20 x 28, for recovering the roof of the United States Custom House, in that city, and advise us that there has been a growing demand for these Plates on important work.

THE WAUKESHA SHEET STEEL COMPANY, Waukesha, Wis., have under consideration the erection of a Tin Plate plant, to be run in connection with their other departments.

THE PARISH & BINGHAM COMPANY, Cleveland, Ohio, manufacturers of Metal Stampings, are having plans prepared for a two-story building, 50 x 300 feet, and they will also add another story to their present plant. The company are preparing to go into a new line—the production of Lithographed Tin Boxes, for which there is an immense demand. They have recently installed considerable machinery for this work, and are now occupying a large factory formerly used by the O. P. Clay Stampings Company for this branch of their business.

THE J. M. ROBINSON MFG. COMPANY, Cincinnati, Ohio, advise us that they have recently made a large machine for the Art Metal Construction Company of Jamestown, N. Y., intended for bending Sheet Metal in various shapes. Among the articles manufactured by the Art Metal Company are furnishing for library buildings in which nothing but Sheet Metal is now used. Sheet Iron can be bent so as to make it very strong, and able to bear up a great weight by being corrugated and treated in other ways which have been adopted for strengthening it.

THOMAS P. H. WHITELAW is forming a rolling mill company under the name of the Oakland Steel Works at East Oakland, Cal. The works will be designed to roll Sheets and to manufacture Corrugated and Galvanized Iron. The addition of Tin Plate mills is also contemplated after the Sheet mills get into operation, as well as a plant for manufacturing Tin Cans.

THE statement that the Youngstown Iron, Sheet & Tube Company would tear down Alice Furnace at Sharpsville, Pa., which they recently bought, and build a larger furnace is incorrect. The company bought Alice stack to supply their present wants and will begin the erection of a new blast furnace at Hazelton, where their works are located, in the early spring.

TRADE NOTES.

FARNHAM & JOHNSON, have succeeded Drew & Gale, 191 High street, Boston, as dealers in Metals, and will continue the business at the same location.

THE TURNER, VAUGHN & TAYLOR COMPANY, Cuyahoga Falls, Ohio, have issued a 16-page illustrated catalogue of their Chain Machinery, including the new Edgecombe Hammer, No. 1 Lightning Winder, No. 1 Link Cutter, Foot Hammer and Gas and Oil Furnaces for heating links for welding.

THE ILLINOIS PURE ALUMINUM COMPANY, Lemont, Ill., will spend about \$50,000 during the coming year in making improvements to their plant. The floor space will be considerably increased and a number of new machines installed. They make Aluminum Ware, Steam Jacketed Kettles, &c.

THE W. J. CLARK COMPANY of Salem, Ohio, report a lively demand for their improved Hose Couplers, known as the Quick as Wink. Their use on compressed air hose in shops where pneumatic tools are used is said to work a great saving of time. The W. B. Pollock Company, Youngstown, Ohio, having tried them in their extensive boiler works, have decided to discard the common coupler and use the Quick as Wink instead. Their order has been placed for 180 sets.

THE firm of McClamrock Brothers, wholesale and retail dealers in Mantels, Grates, &c., have been merged into the McClamrock Mantel Company, with a capital of \$25,000. The business of the concern will be considerably enlarged and extended.

THE SOUTHERN METAL COMPANY of Orangeburg, S. C., have been incorporated with a capital stock of \$10,000, to manufacture Agricultural Implements and Sheet Iron Specialties.

THE BRADFORD METAL STAMPING & MACHINE COMPANY of Bradford, Pa., have been incorporated with a capital stock of \$20,000.

H. M. SHIMER & Co., smelters and refiners of Babbitt Metal, Brass and Spelter, Philadelphia, Pa., have purchased a plot of ground 66 x 185.6 feet, at the northeast corner of Nineteenth street and Washington avenue, in that city. A one-story brick and corrugated iron building, 66 x 80 feet, will be erected for smelting purposes, and a furnace installed which will enable them to produce from 30,000 to 40,000 pounds of ingots per day.

THE KANSAS CITY DIE & MOLD COMPANY, recently organized, have located at 604-608 West Fifth street, Kansas City, Mo., where they are prepared to make all kinds of Dies and Molds. They make a specialty of Glass and Soap Molds, Embossing, Cutting and Stamping Dies. The proprietors are C. F. Bartholomees and G. Magnien.

THE MONSON-BURMAH SLATE COMPANY of Portland, Maine, are reported to be shipping their products, including Slate Sinks and Mantels, to Great Britain and Germany.

THE EXCELSIOR ASBESTOS MFG. COMPANY of New York City have been incorporated with a capital stock of \$25,000 by H. S. Predmore, B. F. Boscoe and L. J. Beerbower of New York City.

THE WATERBURY BRASS COMPANY, Waterbury, Conn., to meet the demand have increased their facilities for producing Brass Brazing Wire, and are now in a position to promptly supply the requirements of this trade. They advise us that a careful study of the use of this material and the knowledge gained through the production of a large variety of Solders has led to the manufacture of an excellent Wire. They would be pleased to furnish samples of this material as well as of the several grades of Spelter Solder manufactured by them upon request.

THE WILKE MFG. COMPANY, Anderson, Ind., manufacturers of the Plate Glass Interior and White Glazed Tile Refrigerators, have been compelled by the increased demand for their line of goods to build a brick addition, 56 x 156 feet, with a 7-foot basement, to their factory building, to be used for manufacturing and storage purposes, and are now in a better position to fill orders.

An idea of the remarkable growth of the International Correspondence Schools, at Scranton, Pa., during the ten years of the existence of the enterprise may be gained from the following statement given out by the institution: The total enrolled membership of the school, with their families, on the basis of five persons to a family, would people a city of nearly 2,000,000 population. The postage paid by the schools amounts to nearly \$300 a day, or \$100,000 a year. As the schools pay the postage to the student only, the above figures represent but half the revenue that the United States Post Office derives from the schools. Ten thousand checks are used monthly to pay the company's bills. The schools are the largest producers and consumers of books, bound in cloth or half leather, in the United States. One hundred and thirty-two persons are employed in Scranton in the publishing department, and two of the larger printing houses in New York City are mainly supported by the work of the institution. The number of pages of published matter distributed per annum amounts to over 24,000,000. At the present time the schools are erecting in Scranton what will be one of the largest private printing plants in the world. It will be 167 x 460 feet and four stories high, containing over 6¼ acres of floor space.

DISPENSING WITH RECEIPTS FOR REMITTANCES.

The past year has developed a change in the business routine of some of the large Hardware jobbing houses, by means of which an economy is effected. The reform in question is the giving up of sending receipts for remittances, in view of the fact that the check or draft is a sufficient voucher. In this way a saving in labor is effected, as well as in postage. This reform was put into operation last summer by prominent Western jobbing houses, and is now being taken up by others. It is generally referred to as working satisfactorily and occasioning very little friction in trade. The reasons for this action are thus given in a notice which was sent out to the customers of the house issuing it:

Beginning July 1 we will discontinue sending receipts for remittances, except those made in currency.

In explanation of the above would state that our object in so doing is to avoid what we consider an unnecessary labor and expense. For some years past we have been making our remittances without requiring acknowledgments of same, as we consider an indorsed draft answers all purposes of a receipt, and in case of a money order, or express money order being sent, the proof is in your town.

Remittances at all times should be made, if possible, by bank draft, express money order or post office order. Currency should never be sent if avoidable, and in case it is sent, it should invariably be by registered letter.

This action is in line with the tendency of the times. The plan is being adopted rapidly by many large concerns, and we believe it will soon be a very general custom, simply because it is in the line of economy and saving in which all will naturally share, and in which, therefore, all are equally interested.

Norvell-Shapleigh Hardware Company, St. Louis, go into the matter more fully and explain the reasons for their action in the following announcement:

Beginning August 1 we will discontinue sending receipts for remittances, except when made in currency.

This plan is being adopted very generally throughout the mercantile world, for the reason that it is in the line of economy and saving, in which, as all will share, all should be equally interested.

As the ordinary forms of remittances are in themselves their own best receipts, the sending of acknowledgment by the house receiving them is unnecessary, and is, therefore, "waste." Modern business methods are largely in the direction of preventing waste.

As far as possible all remittances should be made in one of three ways: Bank draft, express money order or post office money order. Records show that not one remittance out of 10,000 goes astray, and in the few cases where they do fail to reach their destination, if it is in one of the above forms, the proof of its having been sent is in your own town.

If you send us a draft, we have to indorse it before it will be accepted by our bank; our bank has to indorse it before it will be accepted back by the bank in your town and, therefore, this draft carries on its back the entire history of the transaction. If any question should arise about it, your bank will gladly furnish the necessary information. In the case of express and post office money orders, you not only get a receipt from the office, but that office can trace the money order through for you and show payment if desired.

We shall, of course, continue acknowledging the receipt of all remittances made in currency, whether registered or not.

The fact that receipts are not necessary has for a long time been recognized by business men, and many commercial houses have for years been refraining from asking them. The present reform is, however, a step in advance, as the trade are given to understand that receipts will not under ordinary circumstances be sent unless specially requested. The announcement made in regard to this matter by W. B. Belknap & Co., Louisville, Ky., will be of interest in this connection:

Customers will please note that, in accordance with a growing custom which readily recommends itself to business men, we will send receipts for remittances only when such are especially requested.

We have tried for the past ten years ourselves the plan of not asking for receipts; on the contrary, where we send checks we ask that no acknowledgment be made, and have yet the first case of complication to arise therefrom. In the light of this experience, we ask our friends to permit us to do away with this needless expense and multiplication of papers which all of us wish to avoid.

We have no remittances to speak of in currency, and as checks, drafts and express money orders are always returned to the sending point after being paid and canceled, you have at your hand all the necessary proof of payment, should question arise.

So little store is set by the old form receipt, that our ingenuity is taxed to put it in such form as will save it from the waste paper basket. Of course, special forms, vouchers, settlements by trustees and administrators, &c., will be acknowledged in the usual formal way, as will the remittances of such customers who particularly desire it.

The W. Bingham Company, Cleveland, Ohio, who have recently announced their adoption of the same policy, thus explain the matter to their customers:

No receipts for remittances by check will be sent by us after December 1, 1901, except on request. Checks bearing our indorsement are sufficient receipts.

Vouchers and special forms with remittances will be interpreted as a request for a receipt.

We adopt this plan following a fast growing custom with business houses who find that it works admirably, and saves much labor.

There seems to be little doubt that this movement will still further extend itself throughout the trade, in view of its advantage as diminishing the labor and expense of doing business.

Safety Screw Staple.

William F. Schall, 61 Barclay street, New York, for whom Frederick Pfeifer, 88 Chambers street, New York, is the sole selling agent, is manufacturing the Safety

Safety Screw Staple with Slotted Counterplate, Three-fifths Size.

screw staple here illustrated. The feature of this staple is that it can be driven into or through a board, and quickly secured on the inner side by means of a rectangular slotted counter plate and two threaded nuts. It is especially recommended for store rooms, coal bins and similar places in apartments, flat houses, &c., which are much frequented by sneak thieves, who with a jimmy quickly and noiselessly withdraw the usual staple even when clinched. The sharpened points, if so desired, can be as quickly protected by forcing a piece of soft wood over them, holding it in position by driving a nail in the center of the piece through the slotted counter plate. The exact outer dimensions of the staple are $2\frac{1}{2} \times 1\frac{1}{8} \times 3-16$ inches. The wrought iron counter plate is $2\frac{1}{2} \times \frac{5}{8}$ inches outside, with a rectangular slot or opening $1\frac{3}{4} \times \frac{1}{4}$ inch, through which the sharpened legs of the staple pass.

The *Post* of Houston, Texas, says, regarding the output of the Beaumont oil fields: "The Russian field is said to have marketed 365,000,000 barrels of oil during 1900. If the Beaumont field can get 150 more oil cars into service within the next two or three months it will market more oil during the coming year than was marketed in Russia in 1900. The quantity marketed by the Russian field was equal to 153 cars per day, and there is no doubt that the Beaumont field will ship more oil than that if the cars can be procured."

THE LETTER BOX.

Inquiries in regard to practical questions of general interest are invited, in reply to which we shall be glad to receive suggestions and information from our readers.

Correspondents are requested in all cases to give their names and addresses, which will not, however, be published or disclosed without their consent.

RETURNING CONDENSATION TO BOILER.

From E. T., Hilton, N. Y.—I have a customer who wishes to use a steam boiler for heating an evaporating chamber which is placed at one side of the boiler and above it, as shown in Fig. 1. Can the steam be carried to the pipes in the evaporator, and will the condensation return to the boiler, provided the return pipe has suffi-

Returning Condensation to Boiler.—Fig. 1.—Coil in Evaporating Chamber.

cient pitch to cause the water to flow? It is also desired to use the steam from the boiler to boil cider in a vat, which is about 5 feet distant from the boiler and slightly above it, as shown in Fig. 2. Can the condensation be brought back from the heating coil in the vat? Will it be necessary to use a trap or a valve of any kind on the return pipe?

Answer.—There will be no difficulty whatever in returning the condensation in the steam pipes to the boiler in either case, if a sufficient grade is provided for allowing the water to run back freely. The pressure will be practically the same throughout the entire piping system, and inasmuch as the water is heavier than the steam it will fall to the bottom of the pipe, and flow read-

Fig. 2.—Coil in Vat.

ily in accordance with the grading of the pipes. The steam main from the boiler should be large enough to feed the piping in the evaporating chamber and the boiling vat under all conditions, and the piping should be arranged so that the steam can flow through it freely. It may be better to use a check valve on the return pipe, particularly the return from the boiling vat. If steam were turned in the heating coil in this vat when it was filled with cool cider, the steam might condense quickly and create a vacuum which would tend to lift the wa-

ter from the boiler through the return pipe. A check valve on the return pipe would overcome any such tendency.

HEATING MAINS IN OUTER WALLS.

From Experience, St. Paul, Minn.—Having worked in British Columbia and knowing something about the cold weather there, I would suggest to "Y. F.," who asks in *The Metal Worker* of December 21 as to the advisability of running a hot water riser up within an outside wall, that it would be a very risky piece of business. Of course the pipe might be well insulated with some kind of pipe covering, but as a rule pipes within an outside wall are brought directly into contact with it, so that the heat intended to be conveyed to registers is absorbed by the wall, greatly reducing the efficiency of the system. Further, in case the fire should get down, the probability of a main freezing in an outside wall is very much greater than if it was run up within the inner wall, or inside of the building proper.

HOW SHALL BOILER BE RATED?

From J. S. J.—We present herewith a sketch of a steel boiler, which will be incased in brick, the idea being to have the flames pass up from the fire through the flues, then around to the front, where they will pass down and around the rear of the boiler and thence to the chimney. The dimensions of the boiler are as follows: The shell is 58 inches high and 51 inches in di-

How Shall Boiler Be Rated?

ameter, the fire pot is 46 inches in diameter, the crown sheet begins 28 inches above the grate, and there is a central combustion chamber above the crown sheet, which is 18 inches in diameter and 15 inches high. Surrounding this central combustion chamber there are 48 tubes 3 inches in diameter and 30 inches long. We would like to know how many feet of radiating surface this boiler will supply with steam at 3 pounds pressure, and also how many square feet of radiating surface the boiler will supply with hot water at a temperature of 185 degrees. We would also like to know the method of arriving at the conclusion.

Note.—There are different methods of rating a boiler. Some are by actual test and weighing the condensation of the steam generated in the boiler. A simpler method, and one quite generally used, is to calculate the amount of surface exposed in a boiler below the water line in square feet, and then to estimate that the boiler will carry from 6 to 10 or more feet of surface in the radiation for every square foot of surface it exposes. It will be easy to figure the heating surface, and, assuming that it is about 165 square feet and that each square foot of surface will carry 10 feet of radiation, the boiler should carry 1650 square feet of steam radiation at the pressure mentioned. The water heating capacity of boilers is estimated all the way from 50 per cent. additional surface to double the steam capacity. Assuming that this boiler would carry 75 per cent. additional, it will

readily be figured that it will carry about 2900 square feet of direct hot water radiation. It is probable that this method of arriving at the capacity of a boiler is sufficiently reliable for all ordinary purposes, inasmuch as the boiler is to be used for heating purposes and the manner of firing will vary considerably from what an expert engineer would consider the best practice. The chimneys to which hot water boilers are connected vary considerably in the strength of their draft, and this has a very important effect on the efficiency of the boiler, through the character of the fire that it is possible to maintain in connection with them.

LIFT PUMPS WITH LONG SUCTION PIPES.

From Suction Rod, Maine.—In answer to the inquiry of "C. R." in *The Metal Worker* of December 7, and in comment on the contribution of "T. B." in *The Metal Worker* of December 14, I would remark that "T. B." has said nothing about friction in the 100 feet of 1¼-inch pipe connected with the pump in question. I find this a source of trouble in my territory. In many instances a man who wants a pump goes to a hardware dealer, who never set a pump or repaired one, and who knows nothing about pumps except that he has them for sale, as well as the pipe needed in connection with them. If his customer wants 200 feet of 1-inch pipe and a pump the hardwareman is eager to sell him and he will let the customer do the worrying. I also find a great many tinsmiths who do not understand the setting and repairing of pumps. If I had a pump to set that needed 100 feet of suction pipe, with a lift of 10 to 25 feet, I would use, if my customer would stand it, 1¾-inch lead pipe, certainly not less than 1½-inch iron pipe. I have a case in mind where a man has 200 feet of 1¼-inch pipe attached to a No. 3 pitcher pump. This man wishes to know what the trouble is when he can only get a small amount of water. In regard to check valves on such work, I can see no use for any valves, except the one in the pump, unless, on long distance work, a foot valve is placed at the bottom so as to have less water to draw to fill the pipes in case the pump was repaired, for when one valve is open all are open. Any job, if it has a large pipe which is perfectly tight, will give good results without any extra valves or air chambers. I always use lead pipe when I can, as there are less joints to contend with. I also use 1¾-inch lead pipe, which I cannot get in wrought iron. If "C. R." will use 1¾-inch lead pipe he will get a satisfactory result. I hope he will give the results of his experience, with a description of his piping system in whatever way he may arrange it.

LARGER HOT AIR PIPES.

From M. Y., Maine.—I feel sure that many hot air furnace men do not use large enough hot air pipes, and that if all the hot air pipes on a job were equalized the 12-inch pipe would give better results than the 10-inch pipe, which is so generally used. The use of larger pipes would furnish a larger quantity of warm air in the buildings, and it would not be necessary to run the furnace so hard; consequently there would be an increase in the durability of the furnace and a substantial reduction in the quantity of fuel consumed.

MAKING SHEET METAL BOATS.

From G. I. P., Battle Creek, Mich.—Will *The Metal Worker* please explain how to lay out the pattern for constructing a boat 14 feet long and 4 feet beam, of the regular life boat model, to be put together in narrow strips, or as wide as can be formed consistently with the desired shape?

Answer.—In the construction of boats from wood the shape is molded by the placing of the ribs, especially when boats are small in size. The covering of the ribs is then fitted by the "cut and try method," endeavoring as far as possible to have the top edge of the strips, when placed in position, on a straight line, whatever the shape may be that is necessary to accomplish it. The same method can be adopted in constructing boats of sheet

metal. Suggestions along these lines were presented in articles in *The Metal Worker* of July 22 and August 18, 1889, and May 25, 1901. It is quite probable that a study of the articles referred to will enable our correspondent to construct this boat. Some benefit may be derived and assistance gained from a conversation with some builder of wood boats.

ADULTERATION OF SHEET COPPER.

From B. H. B., Castleton, Ill.—We had a strange experience with one lot of sheet copper, which perhaps some of your readers can explain. An order was received by us to line wooden boxes for holding graphite, and for this purpose we used 14-ounce tinned copper. The job proved satisfactory, and later we received another order to line more boxes for the same purpose. This time 12-ounce untinned copper was used, and the results were satisfactory to our customers. When the third order was received we thought that if 12-ounce copper had answered the purpose, perhaps 10-ounce would do as well, and leave us a larger margin of profit. In a comparatively short time after the job was delivered complaints were made that something was wrong, and upon investigation we found that the copper was eaten through in many places and had a rotten appearance. We sent a sample of the damaged copper to the wholesaler from whom it was purchased, and he, in turn, forwarded it to the manufacturers from whom it was bought.

The report came back that the indications were that the copper had been subjected to severe heat, and that no copper would stand abuse of that kind. We wrote that as the copper was used as a lining for wooden boxes we could not see why the boxes had not burned, and asked the manufacturer to guess again. The matter was then turned over to the manufacturer's chemist, who reported that while he had not analyzed the copper, to him it had the appearance of being adulterated. The result of the complaint was the replacing of the copper by the manufacturer. This we used for lining some more boxes for the same purpose, with good results. While the possible adulteration of copper was a new idea to us, it may not be to some of your readers.

Answer.—Sheet copper is not always pure. There are at least two or three grades of ingot copper on the market; the poorer grades being more or less adulterated with iron or other metals, which are found very difficult of elimination by the smelting process. Manufacturers take advantage of prices for profit, and sometimes may make mistakes in mixtures from open market ingot supply and thereby put out a bad batch of sheets. There is also a possibility that the graphite packed in the boxes in question had been treated with acid for the removal of free iron and had not been thoroughly washed, which would quickly affect the 10-ounce copper. A mistake at the graphite works may have been at the bottom of the trouble, for pure graphite should have no action upon copper of any quality.

GALVANIZED IRON ROOFING ON THE SEA COAST.

From Cortright Metal Roofing Company, Philadelphia, Pa.—Referring to the article on "Galvanized Iron Roofing on the Sea Coast," which appeared in *The Metal Worker* on December 14, we would say that if "Roofers, Atlantic Sea Coast," will send us his name and address, we will furnish him with information concerning a system of roofing which is especially adapted for the work he is inquiring about.

WHERE SHOULD CHURCH FURNACE BE LOCATED?

From M. Y., Maine.—I would like to have the opinion of some of the furnace readers of *The Metal Worker* as to where a hot air furnace should be placed in the basement of a church, when a direct pipe is carried from the top of the furnace to the register in the church floor. I am uncertain as to the point of location of such a furnace and would like to hear from others. Will it really make any great difference where the furnace is placed, provided it is a first-class furnace and of ample size?

TRADE REPORT.

MARKET SUMMARY.

Pig Tin declined 1c., but closed firmer.

Copper is dull and weak.

Pig Lead is very quiet at the lower prices named last week.

Spelter is dull and unchanged.

Antimony is without change.

Nickel continues firm and unchanged.

Aluminum is active at former prices.

Tin Plates are quiet, and without feature of interest.

Sheets are still in large demand, with no change in prices.

Sheet Copper is unchanged in price and very quiet.

Foundry Pig Iron is being bought heavily, and prices are very strong, with upward tendency.

Old Metals are dull, Scrap Brass and Copper being specially quiet at lower prices.

Hardware is more quiet, but firm prices are noted.

Eave Trough and Conductor Pipe are 10 per cent. lower in price.

Plumbers' Brass Work prices are unchanged so far, notwithstanding the decline in Copper.

Soldering Nipples are the subject of a new price-list just issued.

Lead Pipe prices have been reaffirmed.

Wrought Iron Pipe is unchanged in price and in good demand.

Copper and Brass Goods are still quoted at former figures, but lower prices are looked for.

Shot has been reduced in price.

Wire Nails are irregular and rather lower in price.

Cut Nail prices have been reaffirmed.

Window Glass is irregular in price, with uncertain outlook as to the future.

White Lead has been reduced in price $\frac{1}{4}$ c.

Linseed Oil is 2c. a gallon higher.

Spirits Turpentine is firm and higher.

METAL MARKET.

NEW YORK, December 26, 1901.

Pig Tin.—A further decline in the Pig Tin market occurred in the early part of the week, but a turn for the better in the London market stiffened prices here before the close. Very little trading for either consumptive or speculative account was done. Jobbers' prices for Straits Pig in small lots were quoted at $24\frac{1}{4}$ c. to $24\frac{3}{4}$ c. per lb.

Copper.—The Copper market has remained dull and unsettled, and although no further reductions in price were made, the announcement of still lower prices was momentarily expected by the trade. It is rumored that further reductions are likely to be made at any time. The market is thoroughly unsettled, and no one can foretell what will happen. As a consequence transactions were extremely light. Prices are largely nominal, but Lake Ingot is said to have been sold in a retail way at 14c. to $14\frac{1}{2}$ c. per lb., and Casting Copper at $13\frac{3}{4}$ c. to 14c. Exports of Copper thus far this month have amounted to 5632 tons, which is small. Imports during the same period foot up to 2622 tons.

Sheet Copper.—No change in the price of Sheet Copper has yet been announced, but there is little doubt that the sharp break in the price of Raw Copper will be followed before long by a reduction in the price of the manufactured article. Consumers, being satisfied that lower prices are imminent, have been buying very sparingly, and the manufacturers, while quoting for spot delivery

at former figures, are advising their customers against placing orders for future deliveries at present quotations.

Pig Lead.—If the cut in prices made last week was calculated to increase interest in buying, it has failed completely. Very much the same feeling is prevalent now among consumers of Lead as the Copper consumers have shown for some time. The former are more cautious than ever, what faith they had in the stability of prices having been so severely shaken that they purchase only according to their absolute and immediate needs. Business has been exceedingly dull. Jobbers quote small lots of American Pig at 4.45c. to $4\frac{1}{2}$ c. per lb.

Spelter.—The recent developments in other metals have caused a quite natural degree of caution among consumers of Spelter, who are buying merely to fill their current needs. Business in this metal has been considerably lighter during the week under review. Meanwhile prices are unchanged, and without any indication of a decline in the near future, as stocks are very light, and consumers are understood not to have covered their wants very far ahead. Good Western brands, in small lots, are quoted by jobbers at $4\frac{1}{2}$ c. to $4\frac{3}{4}$ c. per lb.

Sheet Zinc.—The demand for Sheet Zinc is of moderate proportions and prices are unchanged, jobbers quoting 600-lb. lots at $6\frac{1}{4}$ c. and smaller quantities at $7\frac{1}{4}$ c. per lb.

Antimony.—The market is unchanged and the demand is of fair proportions. Cookson's, in small parcels, is quoted at $10\frac{1}{2}$ c. to 11c. and Hallett's at $8\frac{1}{4}$ c. to $8\frac{3}{4}$ c. per lb.

Nickel.—Is unchanged, continuing on the basis of 60c. to 65c. per lb. for small lots.

Aluminum.—The manufacturers of Aluminum report a continued active and steady demand for this metal. Prices are without change. Small lots of No. 1 Ingot guaranteed 99 per cent. pure rule at 37c. per pound, and 100-lb. lots at 35c.

Tin Plates.—There is nothing fresh to be reported in connection with this market. Business is fair for the season, and prices are without change. The American Tin Plate Company are continuing to take orders for delivery in the first quarter of next year at the figures ruling for some time past. American Bessemer Coke Plates, IC, 14 x 20, in small lots, delivered at New York and corresponding points, rule at about \$5.25 to \$5.50 per box.

Sheets.—The market for Sheets, while still strong, with prices in general showing no decline from the level maintained for some weeks past, shows some slight indication of approaching softness, owing to the increased output, which is beginning to come into the market from the new independent Sheet mills that are starting operations. Some of these new mills are said to be anxious for orders and to be willing to make slight concessions in prices in order to obtain desirable contracts. However, there is still a very large demand for Both Black and Galvanized Sheets, and nearly all of the mills are comfortably filled up with orders for some little time to come. Deliveries are beginning to come in rather more freely to the local market, but available stocks of Sheets in jobbers' hands are still quite light. On some of the more popular sizes there continues to be a good deal of scarcity. Jobbers' prices are unchanged, No. 27 One Pass Cold Rolled Soft Steel Sheets being quoted at 4c. to 4.05c., and Galvanized Sheets at 65 to $67\frac{1}{2}$ per cent. off the list.

Chicago advices are as follows: New business is being offered to the mills, although they are still much in arrears and making deliveries on old contracts. Prices are well sustained. Mill shipments of No. 27 Black Sheets are held at 3.15c. to 3.40c., Chicago, and small lots from stock at 3.50c. to 3.70c. Small lots of Galvanized are maintained at 70 to 70 and $2\frac{1}{2}$.

Old Metals.—The market is quiet. Consumers of Scrap Iron are well supplied and are not buying to any extent, and other Scrap Metals are out of favor, owing to the slump in Copper and the weakness of Lead. Scrap Brass and Copper are considerably lower. Dealers are paying about the following rates for moderate sized lots, delivered at New York or corresponding points:

Heavy Copper.....	per lb. 11 c.
Light and Tinned Copper.....	per lb. 9½c.
Heavy Brass.....	per lb. 8 c.
Light Brass.....	per lb. 6½c.
Lead.....	per lb. 3¾c.
Tea Lead.....	per lb. 3¼c.
Zinc.....	per lb. 2¾c.
No. 1 Pewter.....	per lb. 16½c.
No. 2 Pewter.....	per lb. 9 c.
Tin Plate Scrap, per gross ton.....	\$6.00 to \$6.50
Wrought Iron Scrap, per gross ton.....	10.50 to 11.00
Heavy Cast Scrap, per gross ton.....	10.25 to 10.50
Stove Plate Scrap, per gross ton.....	8.00 to 8.25
Burnt Iron, per gross ton.....	5.00 to 5.50

THE PIG IRON MARKET.

NEW YORK.—With possibly one or two exceptions all the larger consumers in this district are now pretty well covered for the first three to six months of next year. Among the transactions closed this week was a round lot for a Connecticut foundry. The market is steady. We quote: No. 1, \$16.35 to \$17.50; No. 2 X, \$15.75 to \$16; No. 2 Plain, \$15.25 to \$16; Tennessee and Alabama brands, No. 1 Foundry, \$16; No. 2 Foundry, \$15.25; No. 1 Soft, \$16; No. 2 Soft, \$15.25; No. 3 Foundry, \$14.75; No. 4 Foundry, \$14.25.

CHICAGO.—The sales of the week have principally consisted of Southern Foundry Iron. These include one 3000-ton contract, several 1000-ton lots and quite a number of orders of 500 tons. More of the Southern furnace companies are advancing their prices. It is expected that the market will shortly show a general advance of at least 50c. Stocks at Southern furnaces are getting down to a very low point. Trouble is constantly experienced in securing deliveries from the South because of the shortage of cars. The local situation is particularly strong. The scarcity of Coke has caused two more furnaces producing Foundry Iron to be banked and danger is imminent that more will have to suspend operations if the supply does not improve. Inquiries are numerous, indicating a continuance of the buying movement. We quote as follows:

Lake Superior Charcoal.....	\$18.50 to \$19.25
Local Coke Foundry, No. 1.....	16.00 to 16.50
Local Coke Foundry, No. 2.....	15.50 to 16.00
Local Coke Foundry, No. 3.....	15.00 to 15.50
Local Scotch, No. 1.....	16.00 to 16.50
Ohio Strong Softeners, No. 1.....	17.60 to 17.85
Southern Silvery, according to Silcon.....	16.15 to 16.40
Southern Coke, No. 1.....	15.65 to 16.15
Southern Coke, No. 2.....	15.15 to 15.65
Southern Coke, No. 3.....	14.65 to 15.15
Southern Coke, No. 1 Soft.....	15.65 to 16.15
Southern Coke, No. 2 Soft.....	15.15 to 15.65

PHILADELPHIA.—There is no relief from the scarcity which has been felt for a month past, and in fact in some lines it is greater than ever. Foundry Irons can be picked up here and there, but the supply for quick delivery is too restricted to meet all requirements. For the first three or six months of the coming year prices are nominally unchanged. Makers deprecate any premature advance, but they are not pushing business, although from regular customers they accept moderate lines of business at about the same prices as have been quoted for two or three weeks past, but the disposition is very conservative, and both sides wait the trend of events before making very heavy commitments. The general impression is that present quotations will continue until well into January, but there is no doubt that a very optimistic feeling prevails. Prices are more or less nominal, but the extreme figures both ways would be about as follows for Philadelphia and nearby points: No. 1 X Foundry, \$16.25 to \$16.50; No. 2 X Foundry, \$15.75 to \$16.25; No. 2 Plain, \$15.35 to \$15.65.

PITTSBURGH.—The car situation is getting worse. At the present time eight or ten furnaces in the Mahoning and Shenango valleys are banked for want of Coke, and it is likely that some stacks will have to blow out. Foundry Iron is very scarce. Furnaces are piling Iron in some cases for want of cars and the situation is critical. We quote No. 2 Foundry at \$16 to \$16.25 and No. 1 Foundry at \$16.50 to \$16.75, f.o.b. cars Pittsburgh.

CINCINNATI.—There has been some very good selling all along the line in the Pig Iron market. When the season is considered the buying may be called heavy. A number of contracts are reported for deliveries extending to December, 1902. In spite of the fact that a number of furnaces declare themselves out of the market at the present prices, the quotation sheet remains unchanged. This is owing to the attitude of the large Southern interests in refusing to advance their figures. It is apparently safe to say that the market is well under the control of a well balanced conservatism. A fair trade is looked for throughout the next week. We quote, f.o.b. Cincinnati:

Southern Coke, No. 1.....	to \$15.00
Southern Coke, No. 2.....	to 14.25
Southern Coke, No. 3.....	to 13.75
Southern Coke, No. 4.....	to 13.25
Southern Coke, No. 1 Soft.....	to 15.00
Southern Coke, No. 2 Soft.....	to 14.25
Southern Coke, Gray Forge.....	to 13.25
Southern Coke, Mottled.....	to 13.25
Ohio Silvery, No. 1.....	\$15.60 to 16.10
Ohio Silvery, No. 2.....	15.10 to 15.60
Lake Superior Coke, No. 1.....	to 16.60
Lake Superior Coke, No. 2.....	to 16.10
Lake Superior Coke, No. 3.....	to 15.60

CHICAGO REPORT.

Scrap Iron and Steel.—Trade is light. Cast Scrap is firm, but other classes of material are inclined to weakness. We quote dealers' buying prices for carload lots, Chicago delivery, as follows:

	Per net ton.
Country Wrought Scrap.....	\$11.00 to \$11.50
Machinery Cast.....	10.50 to 11.00
Malleable Cast.....	10.00 to 11.00
Stove Plate (free from burnt).....	8.00 to 8.50
Burnt Iron and Grate Bars.....	5.50 to 6.00
Sheet Iron and Hoops.....	6.00 to 7.00
Plow Steel.....	to 10.00
Breaking Stock.....	9.00 to 10.00
No. 2, such as Shovels, Hoes, &c.....	to 7.00
Old Boilers—whole (Iron).....	6.50 to 7.00
Old Rollers (Iron) cut in single Sheets and Rugs.....	10.00 to 11.00
Old Gas Pipe and Boiler Tubes.....	10.50 to 11.00
Cast Borings.....	4.50 to 5.00
Turnings.....	9.50 to 10.00
Horseshoes.....	12.00 to

Old Metals.—Business is demoralized by the great decline in Ingot Copper. Nothing is doing. Dealers quote buying prices on small lots as follows:

	Per lb.
Copper Wire and Heavy.....	10 c.
Copper Bottoms.....	9 c.
Copper Clips.....	10 c.
Red Brass.....	10 c.
Yellow Brass.....	7½c.
Red Brass Borings.....	9 c.
Yellow Brass Borings.....	6½c.
Light Brass.....	6½c.
Pipe Lead.....	3.55c.
Tea Lead.....	3 c.
Zinc.....	3 c.
Tin Foil.....	21 c.
Pewter, No. 1.....	16 c.
Pewter, No. 2.....	14 c.

Old Rubber.—Dullness still prevails. We quote as follows:

	Per net ton.	Per lb.
Garden Hose.....	\$25.00
Air Brake Hose.....	46.00
Rubber Shoes.....	7 c.
Rubber Car Springs.....	5½c.
Inside Bicycle Tubing.....	22 c.
Outside Tubing.....	6¾c.
Black Rubber.....	4¼c.
White Rubber.....	8¼c.

Rags.—Dealers quote buying prices of good Country Mixed Rags, Chicago delivery, at 75c. to 85c. per 100 lbs. in any quantity.

Anthracite Coal.—The supply is somewhat better, as railroads are beginning to get enough cars to make fairly satisfactory deliveries. Trade keeps up very well. Prices are unchanged, as follows:

	Grate.	Egg and Stove.
Chicago.....	\$5.75	\$6.00
Milwaukee, Wis.....	5.75	6.00
St. Louis.....	6.20	6.45
Kansas City, Mo.....	8.25	8.50

The excellent condition of the business interests of Chicago is forcibly demonstrated by the experience of one of the largest owners of manufacturing and warehouse property in the city. He says that in 12 years' experience he has never seen such an enormous demand for manufacturing or warehouse facilities, having numerous inquiries for space which cannot be considered. He finds many parties seeking capitalists willing to construct buildings for their use on a percentage basis.

THE HARDWARE TRADE.

In both mercantile and manufacturing establishments the presence of the holiday season is emphasized in various ways. Manufacturers find a marked falling off in the immediate demands for goods, as the requirements of the trade for the year are presumably covered, and merchants are refraining from buying unnecessarily just before the annual inventory. With the exception of a few belated rush orders for holiday goods the business which is coming to the manufacturers is for the most part for next season, but even this class of buying is limited, and the volume of current business accordingly shows considerable falling off. Few manufacturers, however, regret this. Many of them have only broken stocks in their warehouses, and not a few are seriously behind their orders. An opportunity to get in shape for spring trade is therefore not unwelcome. With local merchants, especially those who go into the finer goods and the lines which receive attention from holiday shoppers, the present season is one of unusual stir and activity, and many report an exceedingly satisfactory business of a type which is more than usually profitable. In anticipation of the passing of the holiday rush, preparations for the annual stock taking are being made, which will show in black and white the results of the year's effort.

There is little general change in the tone of the market, so far as prices are concerned. The break in copper will probably have some effect on goods of which this metal is the material, but the market has not as yet taken its proper level, as the trade are waiting to see where the prices of ingot copper will settle. The break is not unwelcome to the trade, as a whole, who have long looked upon it as inevitable, the natural result of an attempt to keep prices at an unreasonable height. The strength of the iron market is a feature of prime importance in the situation. This tends to give firmness to Hardware lines in general. In a few products, owing to exceptional circumstances, there is some weakness, and there is no doubt that some lines which have been scarce will be in better supply. The year, however, draws to a close with very satisfactory conditions, and with much promise for the new year, in the prosperity of which we trust the readers of *The Metal Worker* will have a liberal share.

NOTES ON PRICES.

Plumbers' Brass Work.—The executive officers of the Manufacturers' Association of Plumbers' Brass Goods are said to be making strenuous efforts to hold the prices of their goods at the level agreed on at the last meeting held in Pittsburgh on December 10. The unsettled condition of the Copper market has created an uneasy feeling in the trade, and the officers of the association are afraid that some of their members may become panic stricken and rush into the market with prices much below the combination quotations. The officers are said to be doing everything possible to avert this. So far, their efforts have met with success; due probably to the fact that nearly all the manufacturers are running their factories with Copper bought at 17 cents per pound. It is hoped that the association may be held firmly together until the Copper market has reached a stable base, at which time a meeting will be held and new prices, based upon the new conditions and costs, will be announced. Meanwhile it is understood that the present prices will be maintained, and the members of the association will refrain from sending out prices unless they are asked for, and the inquiry is accompanied with a specification of the goods wanted.

Soldering Nipples.—At the meeting of the Association of Brass Manufacturers, held in Pittsburgh on December 10, the following new list prices were adopted on Soldering Nipples—Male and Female:

Size.	1/2-inch.	3/4-inch.	2 1/2-inch.	3-inch.	4-inch.
Per dozen.	\$3.00	\$4.00	\$28.00	\$40.00	\$72.00

It will be noticed that these are the sizes most in demand and upon which, it is said, there was the least profit to the manufacturers.

Lead Pipe.—The Eastern Lead Pipe Association held a meeting in New York on Friday, December 20, and reaffirmed the price then in effect. The price is 6 3/4 cents per pound, subject to a discount of 20 per cent. to the trade. It is understood that no change in the price of Lead Pipe is contemplated at the present time.

Wrought Iron Pipe.—There is no change in either the cost or conditions of sale of Wrought Iron Pipe, Black and Galvanized. The demand is normal and shipments are being made with a promptness not known for the past year or more.

Copper and Brass Manufactures.—The price of manufactured Copper and Brass products remains unchanged from last week's reports, with the exception of Wire, both bare and insulated, which, not being controlled by an association, now has followed the decline in ingot Copper, Bare Wire being 14 cents per pound, base, with the usual difference for Insulated. Copper and Brass Sheets, Tubes, Rods, Rivets, &c., are still at former figures, although dealers and manufacturers frankly advise their customers to defer purchases, except urgent ones, until after January 1, when it is expected something more definite will develop, or they are executing orders to be billed after the opening of the new year at reductions, or advances, as the case may be.

Shot.—Under date December 17 the manufacturers of Shot announced a material reduction in prices, owing to the changes which have taken place in the cost of raw material. The new prices are as follows, terms net cash 30 days, or 2 per cent. discount for cash in 10 days: Drop Shot, sizes smaller than B, per 25-pound bag. . \$1.35 Drop Shot, B and larger sizes, per 25-pound bag. . . 1.60 Buck and Chilled Shot, per 25-pound bag. 1.60 Dust Shot, per 25-pound bag. 2.00 Freight is equalized with other Shot manufacturing points. On orders for ton lots and upward an abatement of 10 cents per bag of 25 pounds, or 40 cents per 100 pounds, is made.

Maple Sugar Goods.—Chas. Millar & Son Company, Utica, N. Y., make the following quotations on their line of Maple Sugar Goods. The Sap Spouts are subject to the discounts given, the prices on the other goods being net:

<i>Ideal Sap Spout.</i>	
No. 1, Tinned, Open Top, per 100.	\$1.50
No. 1, Tinned, Closed Top, per 100.	1.50
Discounts { Open	25 %
{ Closed	20 %
Terms, cash 60 days from March 1.	

<i>Todd's Patent Cover for Sap Buckets.</i>	
Each	6 cents
In crates of 150, per crate.	\$6.00

<i>Sap Buckets.</i>			
Size.	IC.	IX.	Galv.
12-quart, per 100.	\$13.00	\$15.00	\$17.00
15-quart, per 100.	15.00	17.50	19.50
F.o.b. Utica.			

<i>Sap Pails.</i>			
Size.	IC.	IX.	Galv.
12-quart, per 100.	\$15.75	\$18.00	\$19.50
15-quart, per 100.	18.00	20.25	22.50
F.o.b. Utica.			

<i>Syrup Cans.</i>	
Full gallon, square or round, paneled or plain, with handles, per 100.	\$8.25
1/2-gallon, square or round, paneled or plain, with handles, per 100.	6.75
F.o.b. Utica.	

Twenty-five cents per 100 reduction from list is allowed on Sap Buckets, Sap Pails and Syrup Cans when shipped from factory.

Eave Trough and Conductor Pipe.—A reduction of 10 per cent. has recently been made in the price of Eave Trough and Conductor Pipe.

Wire Nails.—The demand for Wire Nails from store keeps up fairly well, owing, in part, to the fact that local merchants are confining their purchases to small lots. The market does not gain strength, notwithstanding the continued high price of steel, and retail prices are rather lower than of late. Small lots of Wire Nails from store, New York, are quoted at \$2.25 to \$2.30 per keg.

Cut Nails.—At the monthly meeting of the Cut Nail manufacturers prices were reaffirmed for the month of January. On account of the high price of Steel it was not deemed advisable to make lower prices, especially as it was not considered probable that the demand for Nails would thus be increased. The market for Cut Nails in New York is without change. The demand is moderate. Representatives of mills are adhering to the price of \$2.25 for Nails from store. Jobbers are asking the same price generally, but in some instances are selling 2 cents below these figures.

Window Glass.—Reports are conflicting in regard to the probable future of the Glass market, which is dependent upon the position taken by the different combines. It is understood that the outside factories, both East and West, are perfecting arrangements to come in, either with the American Window Glass Company or the Co-operative Federation. It is not yet known whether the Independent Glass Company and the American Window Glass Company will renew their agreement in January or not. If an amicable arrangement can be reached between the three combines it is expected an advance will be made in prices. But if no agreement is reached indications point to lower prices.

White Lead.—Under date of December 20 manufacturers of White Lead, dry and in oil, Red Lead, &c., reduced prices ½ cent a pound. The reduction has been foreshadowed by irregularities in prices, which have been caused by the declining of Pig Lead in foreign markets. The future of the market will probably depend upon the price of the raw material. White Lead in Oil, in a retail way, is quoted at 6½ to 6¾ cents per pound.

Linseed Oil.—The Linseed Oil market hardened under the influence of higher prices for Seed and inquiries for future deliveries. City crushers advanced prices this week 2 cents per gallon. Raw Linseed Oil in small lots is now quoted at 56 to 57 cents.

Spirits Turpentine.—The market for Turpentine is firm at this point and demand moderate. The strength of the market is attributed to reports from Savannah, which indicate an active export demand. Local quotations on small lots are 40 to 40½ cents per gallon.

Cape Cod Commercial Travelers' Association, George E. Hunt, president, will hold their annual banquet and ladies' night at the Parker House, Boston, Friday evening, January 10, 1902. Many of the members of this association are connected with lines represented by *The Metal Worker*, and their annual banquets are always enjoyable occasions. The programme for January 10 includes a business meeting at 2 o'clock in the afternoon and a reception to guests and ex-presidents of the association at 6.30 p.m., and the banquet will be served at 7 o'clock, and several prominent men are expected to make addresses. A fine musical programme also will be provided. President Hunt, in his announcement of the banquet, says: "The past year has been one of prosperity. Our association has made a gain in membership, and has increased its funds in the treasury. As we have made gains in all branches, it is my desire to have a gain of members at the annual meeting and banquet. This will be our fifteenth annual gathering. Let us make it one long to be remembered."

A new record for the erection of the structural steel skeleton of a modern skyscraper has been established by the Thompson-Starrett Company, builders, of New York, at the building corner of Cedar and William streets, almost in the heart of New York's financial center. The structure, 15 stories in height, covers a plot 60 x 130 feet, and on November 9 the task of demolishing the old building which occupied the site was completed. Upon December 4, or in exactly 25 days, including Sundays, the enormous task of erection was completed, and it is stated by the contractors that the building will be ready for occupancy by February 15. The steel was furnished by the American Bridge Company and fabricated in their Trenton branch. Shop details for the work were furnished over a period of four weeks, commencing Sep-

tember 8, and the building was shipped complete in a trifle over nine weeks after receipt of the details.

The Postal Department at Washington has decided that all mail matter is mailable to Porto Rico in the same manner as to any part of the United States. A large amount of merchandise addressed to people in Porto Rico has been held up by the New York Post Office, and a large quantity of it sent to the Dead Letter Office at Washington pending instructions. The postmaster at New York has been notified to forward this mail according to the recent decision.

The imports of merchandise into the United States in the 11 months ended November 30 show an increase of \$39,972,100 over those for the corresponding period of last year, while the exports show a loss of \$3,562,871. The value of the imports for the months mentioned was \$800,424,607 and of the exports \$1,328,493,371, and the balance of trade in favor of the United States in that period was \$528,068,764.

Analysis No. 72,339. New York, Dec. 7, 1896.

We have made a careful examination of a sample of "Agate Nickel Steel Ware" received from The Lalance & Grosjean Mfg. Co., Nov. 30, 1896.

The enamel coating is homogeneous, of extra thickness, and great purity.

It is entirely free from arsenic, lead and antimony—metals so often found in enameled goods.

Very respectfully,
STILLWELL & GLADDING,
Chemists to the New York Produce Exchange.

{ Pierre de P. Ricketts, E.M., Ph.D.
{ John H. Banks, E.M., Ph.D.

Analysis No. 14,180. New York, May 6, 1897.

LALANCE & GROSJEAN MFG. CO.:
GENTLEMEN—As requested by you, we purchased in the open market a sample of "Agate Nickel Steel Ware" and have made a careful chemical analysis of the enamel covering of the same.

We find this enamel is absolutely pure and free from Arsenic, Antimony, Lead and other substances injurious to health. We can therefore recommend it for all culinary and drinking purposes. Respectfully yours,

RICKETTS & BANKS,
Chemists to the N. Y. Metal Exchange.

Patent Applied For.

—THE RULING PASSION.—First Enthusiastic Golfer: "I say, will you play another round with me on Thursday?"
Second Enthusiastic Golfer: "Well, I'm booked to be married on that day—but it can be postponed!"—Punch.

—"CHARLIE, DEAR," said the young mother, "I've decided on a name for baby. We call her Imogen."

Papa was lost in thought for a few minutes. He did not like the name, but if he opposed it his wife would have her own way.

"That's nice," said he, presently. "My first sweetheart was named Imogen, and she will take it as a compliment."

"We will call her Mary, after my mother," was the stern reply.—Selected.

—SHE'S TOO BUSY.—"I've got to stop dictating letters for a while now."

"Why?"

"Our typewriter girl has begun to crochet herself a pink fascinator."—Chicago Record.

The New Metal Worker Pattern Book.

425 Pages. 744 Illustrations.
Size 10 x 13 Inches.

A new treatise on pattern cutting
as applied to all branches
of sheet metal work.

Cloth Bound, Price \$5.

This work contains a collection
of 218 problems and an elaborate
explanation of the principles of
pattern cutting, including Triangu-
lation.

It embodies the problems of the
former Metal Worker Pattern Book,
all of which have been revised, and
many of which have been entirely
rewritten and solved by more ap-
proved methods. To these have
been added 75 new problems and
much other new material and ex-
planatory matter, making this work
a model of completeness in every
respect.

ARRANGEMENT.

In point of arrangement the new
work far surpasses the former one
in that the problems are classified
under three different heads, and
simply indexed, and also that by
means of a table of contents any
required department of the work
can be easily found.

CONTENTS.

While Chapter VI, comprising the
greater part of the work, is devoted
to the solution of problems, the
five preceding chapters thoroughly
explain the principles of pattern
cutting, and place the student in
possession of the preliminary infor-
mation necessary to a thorough
understanding of the subject.

SUMMARY OF CONTENTS.

- I. Terms and Definitions—15 pages.
- II. Drawing Instruments and Materials—13 pages.
- III. Linear Drawing—6 pages.
- IV. Geometrical Problems—35 pages.
- V. PRINCIPLES OF PATTERN CUTTING—25 pages.
- VI. PATTERN PROBLEMS (3 Sections)—325 pages.
 1. MITER CUTTING,
 2. FLARING WORK,
 3. TRIANGULATION.

All Tanners, Cornice Makers and
Sheet Metal Workers should be
provided with a copy of

The New Metal Worker Pattern Book.

Price \$5, post or expressage paid.

THE ELECTRIC CITY GUTTER FORMER.

The Electric City Gutter Former can be bought for 50 per cent. less than other machines intended for the same purpose. This machine will do everything that can be accomplished by any other gutter former. No other machine can do better work. No other machine can do quicker work. The principle of this machine is entirely different from any other. It is more practical. Both the head and the gutter are formed in one continuous operation. You do not waste any time in hard work in getting the body of the gutter in proper shape. Every operation is mechanical. Each length of gutter is formed exactly alike. No other machine is as practical in its operation. No other machine will give as much satisfaction. The low price is very attractive. The machine will perfectly demonstrate our claims. Ask us about it. We gladly furnish information and price on request.

THE DOUBLE TRUSS CORNICE BRAKE CO., - 1453 Niagara St., BUFFALO, N. Y.

Our Improved Double Truss Cornice Brake is the most practical machine of its kind in the market. Let us send you a description of its merits. Our "latest" has a double edge on front leaf for making fine members and corrugations.

DANZER'S LIGHTNING EDGER.

PAT. NOV. 26, 1901.

Built in two sizes, 21 and 31 inches wide. Built for hand, foot and belt power.

It will edge 28 iron and tin for roll or flat seam roofing.

The cheapest, simplest and quickest edger on the market. Will edge from 1/4 to 5/8 inch wide, and has edged a box of 20 by 28 tin in six and three-quarters minutes.

It is a time, labor and money saver.

Manufactured by

DANZER METAL WORKS,
Hagerstown, Md., U. S. A.

For Sale by All Jobbers.

HERCULES SHEARS

make the cutting of sheet metal of heavy gauges an easy task for the mechanic and a profitable operation for the employer. With them a man can cut No. 12 steel with one hand on the lever, leaving the other hand free to guide the stock while cutting elbows, ties and circles, as small as 8 inch radius; this is done without burring or buckling either piece, thus avoiding hammering and straightening, which add to the cost of the product. They split sheets of any width or length up to No. 12 gauge, cut wire or bar-steel 1/2 inch thick, cut off and mitre angle iron 1/2 inch thick, and do it perfectly.

PRICE, - - \$35.00.

Write for Discount.

BUFFALO CIRCLE SHEARS AND EDGER.

Tinsmiths'
Roofers'
Cornice Makers'

TOOLS.

Will cut circles of any size from $2\frac{1}{2}$ to 23 inches diameter, of tin or light sheet metal. No. 26 gauge can be cut, provided the circles are not less than $3\frac{1}{2}$ inches diameter. Smaller circles, down to $2\frac{1}{2}$ inches, can be cut of No. 28 gauge or lighter.

The **EDGE TURNER** will flange circles from 3 to 11 inches diameter. The edge can be turned at right angle.

The **BURRING ATTACHMENT** allows of turning an edge on circles from 5 to 22 inches diameter, beyond the right angle, without using special clamping disks for each diameter.

— ONE OF LIFE'S PUZZLES.—They were discussing gas bills, the subject being a common one at this season, if not a popular one.

"If you use only a little gas, and are as economical as you can be, the bill is just as big," said Hiland.

"Then why not use a great deal!" suggested Halket.

"Well, I tried that, and the bill was three times as much."—Pittsburgh Chronicle-Telegraph.
